1. What this is

xD-Tools is a desktop workbench for retro music media: MiniDisc, CD-R and compact cassette. (The x stands in for M or C - which began as a joke and turned out to be the description.) It started as a label designer and grew into a handful of tools that share one project file:

- **Design** the labels: a MiniDisc's sticker and J-card, a CD's ring label and case inserts, or a cassette's inlay card and a sticker for each side - and export them ready to print and cut.
- **Record** a whole album onto a MiniDisc, from a CD or a folder of files, with a proper track mark at every song.
- **Burn** an audio CD-R from a folder of files, with CD-Text titles.
- **Record a cassette** side by side, with the album split where it fits and the deck left to you - xD-Tools says what to press.
- **Title** a MiniDisc: write the album name and every track name onto the disc itself, so the deck's own display shows them.
- **Drive the deck** from a software remote - transport, track numbers, play modes.

Which medium a project is for is chosen once, when you create it, and everything follows from that: which templates you are offered, what the second page is called, and which entries the Recording menu shows. A MiniDisc project is never offered CD burning, and a CD project is never offered the deck's remote.

The first of those needs nothing but the computer. The other three need **MDRem**: a small RP2040 board that pretends to be a Sony RM-D10P infrared remote and plugs into USB. Everything MDRem-related is optional and switched off until you turn it on.

1. What talks to what: commands over USB, keys over infrared, audio over S/PDIF.

Three separate links, and it is worth being clear about which carries what. The USB cable carries commands and nothing else - no audio ever travels over it. The infrared beam carries keypresses, exactly as a handheld remote would. The audio takes the third path entirely, over S/PDIF, and is needed only when recording.

What you need

For	You need
Designing and printing	xD-Tools, a printer, and - for cutting - a Cricut machine or a steady hand with scissors.
Titling a disc	An MDRem adapter on a USB port, and a Sony MiniDisc deck it can be aimed

	at.
Recording an album	The above, plus a digital (S/PDIF) cable from the computer to the deck - or an analogue one, at a real cost in quality. No other software: xD-Tools plays the album itself.

Everything in this manual was worked out against a **Sony MDS-JE480**. Other Sony decks that accept the RM-D10P keyboard protocol should behave the same way, but the timings in particular were measured on that one.

One thing to understand up front

The deck cannot answer. Infrared only travels one way, and this model's Control A1 bus is not connected inside. So xD-Tools can send a command, but it can never find out whether the deck did it.

That shapes the whole MDRem half of the program: it shows you exactly what it is about to do before it does it, it errs on the side of doing too much rather than too little (clearing an old title with more keypresses than can possibly be needed), and when it reports success it means "everything was sent", never "the disc now says this". Check the deck's display yourself.

2. Getting started

Installing

If you have the packaged build, run `xD-Tools.exe`. From source:

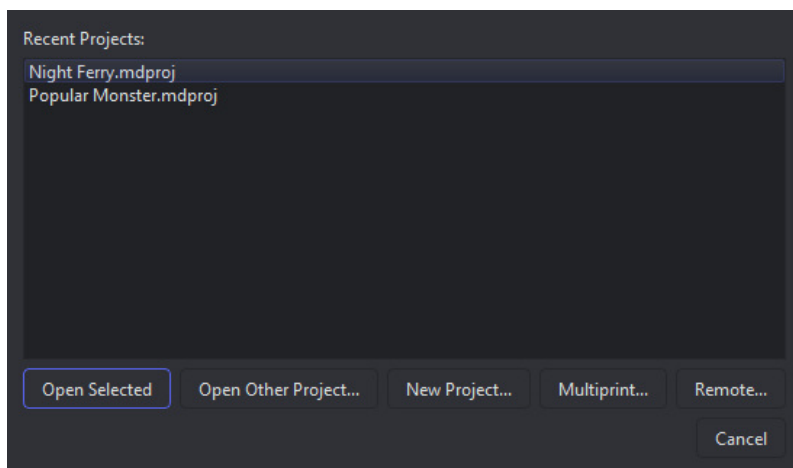

- `python -m venv .venv`
- `.venv\Scripts\pip install -e ".[dev]"`
- `.venv\Scripts\python -m mdtools.main`

Choosing a language

Help > Language offers English, Polski and Japanese. The change needs a restart, and the dialog offers to do it for you.

The startup screen

xD-Tools opens on a short list of what you might want to do: reopen one of the last few projects, browse for another one, or start a new one.

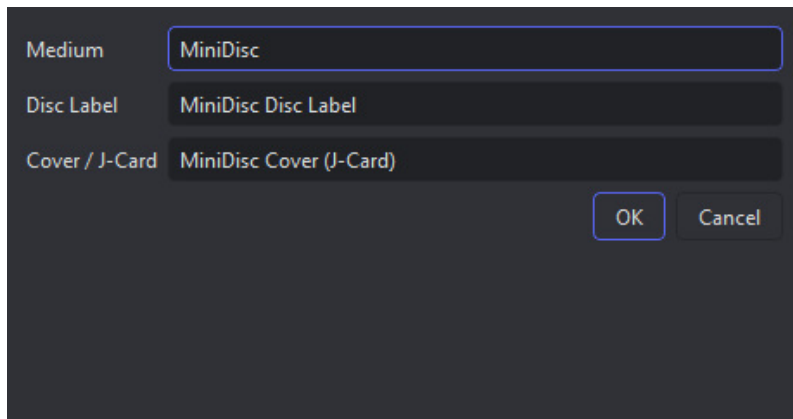

2. The startup screen. Remote... only appears once the adapter is enabled.

- **Open Selected** / double-click - reopen a recent project.
- **Open Other Project...** - browse for a `.mdproj` file anywhere.
- **New Project...** - choose the medium, then a template for each page it has.
- **Multiprint...** - put artwork from several different projects on one sheet of paper. This one does not open a project at all; it is a standalone job.
- **Remote...** - the software remote. Also standalone, and only shown when MDRem is enabled.

A project is its pages plus metadata

How many pages, and which, comes from the medium. A MiniDisc project holds a **Disc Label** and a **Cover / J-Card**. A CD project holds a disc label and a **Case Insert**, and can take a **Case Back** as a third. A cassette project has no disc label at all: it holds the inlay **J-Card** and one **shell label per side**. You switch between them with the dropdown at the top left of the main window.

Alongside the pages, every project holds the album title, artist, year and track list - which the designs, the titling and the automatic layout all draw on.

3. File > New asks for one template per page.

File > Save (Ctrl+S) writes all of that - both designs, the metadata, and any images you placed - into a single `.mdproj` file. Images are embedded, not linked, so moving the project or deleting the original picture cannot break it.

Closing a project

File > Close Project (Ctrl+W) brings the startup screen back rather than quitting, so moving on to another disc is not a trip through relaunching the program. The window's own close button does the same thing. If there are unsaved changes you are asked about them first.

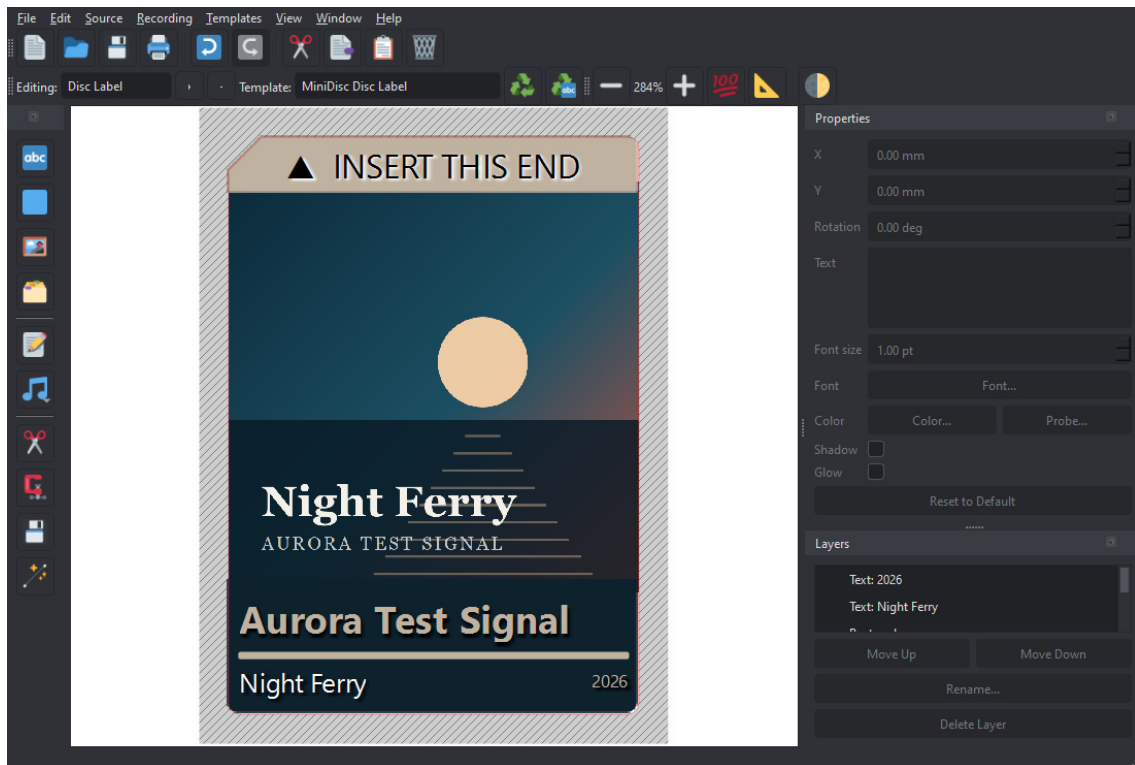

To leave xD-Tools altogether, use **File > Exit**, or cancel the startup screen when it reappears.

Where your projects are saved

The first time you save, xD-Tools proposes **Documents\XDProjects** and a file name built from the album itself - `Skillet - Unleashed (2016).mdproj`. That is the same line the deck is told to display, so the file on your computer and the title on the disc agree with each other.

Other file dialogs start somewhere sensible too: **Add Image...** and cover art open in your Pictures folder, and the SVG, PNG and PDF exports open **next to the project they came from**, so the design and the files that cut and print it stay together.

3. The main window

4. The disc label page, laid out automatically from an album.

The canvas

The middle of the window is the page you are editing, drawn at its real physical size. The red and blue lines are the template's cut and fold lines - they are always drawn on top of your artwork so you can see where the edges are, and they never appear in an exported PNG. The hatched area outside them is the part that gets cut away.

- **Zoom In / Zoom Out / 100% / Fit** on the toolbar, or Ctrl with the mouse wheel, or Ctrl+= and Ctrl+-.
- **Grayscale** previews the page the way a black-and-white print will look, with brightness and contrast sliders that appear next to it. It is view-only - the canvas goes read-only while it is on - and what you dial in here is what Export Print PNG (Grayscale) will use.

Above the canvas are two toolbars. The upper one is the ordinary file and edit row every program has - New, Open, Save, Print, Undo, Redo, Cut, Copy, Paste and Delete - and every button on it is the same command as the menu entry of the same name, with the same keyboard shortcut. The lower one belongs to the page in front of you: which page, which template, the zoom controls and the grayscale preview.

The three panels

Tools (left) adds things to the page: text, a filled rectangle, an image from a file, an image from the built-in gallery, or text taken straight from the project's metadata. **Metadata...** - the album's own details - lives here too, beside the layers it feeds. Below the separator are the four page-wide operations - Clip Layers, Bake Layers, Save as Template and Auto-Layout. Every button is icon-only; hover for its name.

Properties (top right) edits whatever is selected, and shows only the fields that apply to it: text gets its content, size, font and colour; a rectangle gets a colour; an image gets neither. **Probe...** picks a colour off the canvas itself, which is how you match text to a colour in the cover art.

Layers (bottom right) lists everything on the page, front to back. Select, rename, reorder with Move Up / Move Down, or delete. The template outline is not a layer and cannot be touched here.

All three panels can be closed and reopened from the **View** menu, and dragged out into floating windows.

While something is recording

Recording, ripping, burning and title-writing each happen in a window of their own - and while one of them is working, its **close button (X)** puts the window away instead of stopping it. The work carries on: the main window becomes usable again, and a progress bar appears along the bottom, above the status bar. It shows overall progress, the current track where there is one, a **Stop** button, and **Show recording window** to bring the window back.

With nothing running, X closes the window as it does anywhere else. Stopping the work is what **Stop** is for - and the button beside it says **Cancel** while something is running and **Close** when it is not, so the one that throws the work away and the one that merely shuts a finished window never look alike.

The bar stays for as long as that window is open, even once the work itself has finished - it is the only way back to a window you have hidden, so it does not go away until the window does.

Only one of these can run at a time. While one is going, starting another - or closing xD-Tools - is refused: they would be fighting over the same adapter, drive or sound device.

Which project is open

Once a project has been saved, the title bar shows its file name - *Kind of Blue - xD-Tools*. That name is in the taskbar and Alt+Tab too, which is what tells two xD-Tools windows apart. A project you have not saved yet has no file name to show, so it stays *xD-Tools - Retro Media Studio*.

Moving, scaling and rotating

- Drag an item's **body** to move it.
- Drag a **corner handle** (blue square) to resize. By default width and height change independently; hold **Ctrl** to keep the proportions.
- Drag the **circle above it** to rotate. Hold **Ctrl** to snap to 10-degree steps, which is how you get an exact quarter turn.
- Delete or Backspace removes the selection.

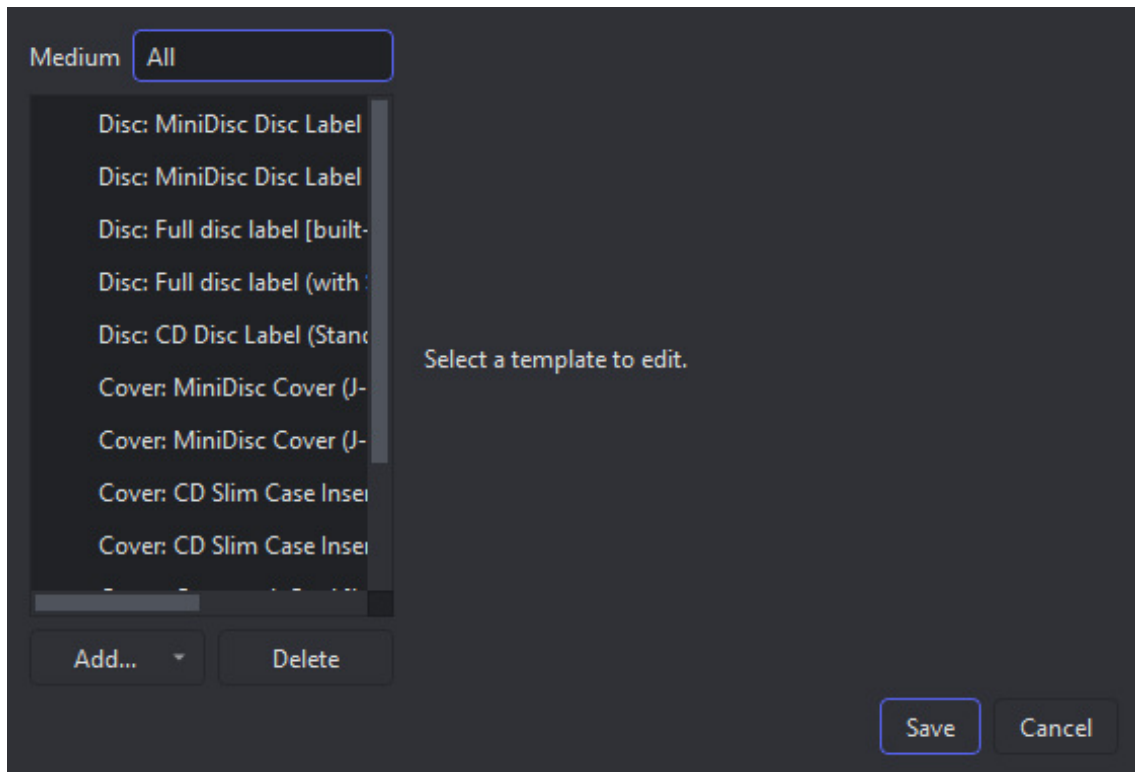

Everything goes through undo (Ctrl+Z), including the automatic layouts.

4. Templates

A template is the physical shape of the thing you are printing: its size, its corners, and where it folds. xD-Tools ships with twelve, across the three media.

Template	What it is
MiniDisc Disc Label	The classic 37 x 52 mm sticker for the front of the disc, with a 3 mm chamfer on the top-left corner and rounded corners elsewhere.
MiniDisc Disc Label (with Slider)	The same, plus a separate small sticker for the cartridge's sliding shutter.
Full disc label	A label covering the whole 71 x 68 mm face of the cartridge, inset by a 0.8 mm margin, with the shutter cut out of it.
Full disc label (with Slider)	The full face plus the shutter sticker, nested into the cutout it sits in. What File > New offers a new MiniDisc project by default.
MiniDisc Cover (J-Card)	The three-panel insert for the case: front, spine, back.
MiniDisc Cover (J-Card + Window)	The same with a 40 x 40 mm window die-cut through the front, so the disc shows through it.
CD Disc Label (Standard Hub)	A ring for the face of a CD-R: 117 mm across with a 35 mm hole for the hub.
CD Slim Case Insert (Front)	A single 120 x 120 mm card -- the front of a slim case, with no fold and no track list.
CD Slim Case Insert (Folded, 2 Panels)	240 x 120 mm creased down the middle: the cover on the right panel, the track list on the left, read through the clear back of the case.
CD Jewel Case Back (Tray Card)	151 x 117.5 mm: a 138 mm panel with a 6.5 mm printed spine either side, for the tray behind the disc.
Cassette J-Card	The 4 x 4 inch inlay card: front, spine and a tuck-in flap.
Cassette Shell Label	90 x 40.8 mm, cut around the reel opening, with the top corners taken off at 45 degrees. One per side.

The **shutter** is the sliding panel on the cartridge that keeps dust off the disc - the deck pushes it aside to reach the surface. It is not the write-protect tab, which is a separate small catch on the cartridge's edge and never gets a label. Because the shutter has to keep sliding, the full-face templates cut a channel for its whole travel rather than just its resting position: a label over that channel would jam it shut.

5. Templates > Manage Templates.

Verified and unverified

A template is marked **Verified** once its dimensions have been checked against a real part. When you are looking at a page whose template is not verified, the status bar says so - measure your own case, correct the numbers here, and tick the box before cutting anything for real.

Making your own

Built-in templates can be edited but not deleted, so File > New always has something to offer. Ones you add yourself can be deleted freely.

Tools > Save as Template... captures the current page's shape *and everything on it* as a new template, so a layout you like can be the starting point for the next disc.

Adding and removing pages

A project starts with two pages -- the disc label and the cover -- and a CD project can have a third: the **case back**, the tray card that sits behind the disc, with a printed strip down each side of the case. It is offered when the project is created (the **Case back** row, which starts at *(none)*), and can be added or dropped later with the +/- buttons on the toolbar, next to the page selector.

+ asks everything about the new page in one window: which page, which template, and whether to start it empty or fill it in from the album straight away. The list of templates follows the page you choose, and the fill-it-in option is greyed out for a template the automatic layout has no recipe for.

The disc label and the cover are part of every project and cannot be removed. Only the optional pages can, and removing one deletes everything on it -- so it asks first, and resets the undo history afterwards.

Changing a template later

The **Template** dropdown on the toolbar, next to the page selector, lists every template available for the page you are on. Picking one of your own -- built with **Save as Template...** or added in the Template

Manager -- switches the page onto it right away. Picking a built-in one asks first, and offers a choice: start the page **empty**, or build it fresh from the project's metadata with **Generated from Metadata**, which works for every template that ships with the program. It is greyed out in one case only: a built-in template you have renamed, which no longer matches any layout by name.

Either way, this **clears the page**: every layer on it is removed and the undo history is reset. The other page and the metadata are untouched.

Rebuilding a page

Two buttons on the toolbar rebuild the page you are looking at from the project's metadata without touching its template. **Regenerate** uses the page's own default fonts and styling, which also makes it the way back after you have tried a different face on it. **Regenerate with Font...** opens the font picker instead: choose a face and the page is redrawn with it there and then, so you see the result before you keep it. Only the family is taken from your choice -- sizes and weights still come from the layout, which fits them to each panel.

Both clear the page and reset the undo history, and both ask before they do. On a page using one of your own templates there is nothing to rebuild -- the automatic layout only knows the built-in shapes -- and you are told so rather than left wondering why nothing happened.

5. Metadata and cover art

Metadata... in the Tools panel holds the album title, artist, year and track list. It is worth filling in even if you are only designing a label: the track list can be dropped onto the artwork as text, and the automatic layout and the disc titling both read from here.

	Title	only on a compi	ie (mm:ss, optional
1	Harbour Lights		4:12
2	Slow Tide		3:48
3	Night Ferry		5:21
4	Cold Deck		4:03
5	Signal Drift		6:15

6. The Metadata dialog, with cover art fetched and a track list loaded.

Three ways to fill it in

1. **By hand.** Add Track, type, and reorder with Move Up / Move Down. Times are optional and written as mm:ss.
2. **Lookup Track List...** searches the iTunes catalogue for the album and artist you typed, and fills in the track list, the year and the cover art. If more than one release matches you are asked which.
3. **Import from Folder...** reads an album folder's own tags - the same tag-reading a recording uses - and fills in the artist, album, year and track list from them, then looks up cover art for it.

Import from Folder... is usually the better source. Those are the actual files you are about to record, with their actual tags, in the actual order - a search can return a different edition with a different track order.

Cover art

A fetched cover is saved in two places: with the project, so it is still there next time you open it, and in the per-user gallery, so **Tools > Insert Asset...** can drop it onto a page like any other image.

If the cover that comes back is wrong, click it. The preview is a button: it opens a file picker so you can point at the right sleeve yourself. Both automatic sources guess, and for a reissue, a compilation or a band with a common name they regularly guess wrong - a search has no way of knowing which pressing you are holding.

When there is nothing good to be found

xD-Tools would rather show no cover than the wrong one. A result has to match the album title **and** the artist before it is accepted: a title on its own is not enough, because a cover version of the title track by somebody else matches that perfectly. When nothing clears the bar, the preview stays empty - which is the honest answer, and one click away from being put right.

There is one more place to look first, though. FLAC files often carry the sleeve inside them, and most rips of your own CDs do. When a search comes back with nothing usable, that picture is used instead. It is certainly the right sleeve for that release; it comes second only because it is often a smaller scan than the 600-pixel artwork a search returns. MP3 files are not read this way.

Putting metadata onto the page

The metadata button in the Tools panel inserts any single field - album, artist, year - or the whole numbered track list, as a text layer. It can also insert the track list as **two side-by-side columns**, which is what a long list needs to fit on a J-card back panel.

6. Automatic layout

The **magic wand** in the Tools panel fills in every page of the project from the album's own artwork and track list. It is the fastest route from "I have a disc" to "I have something to print".

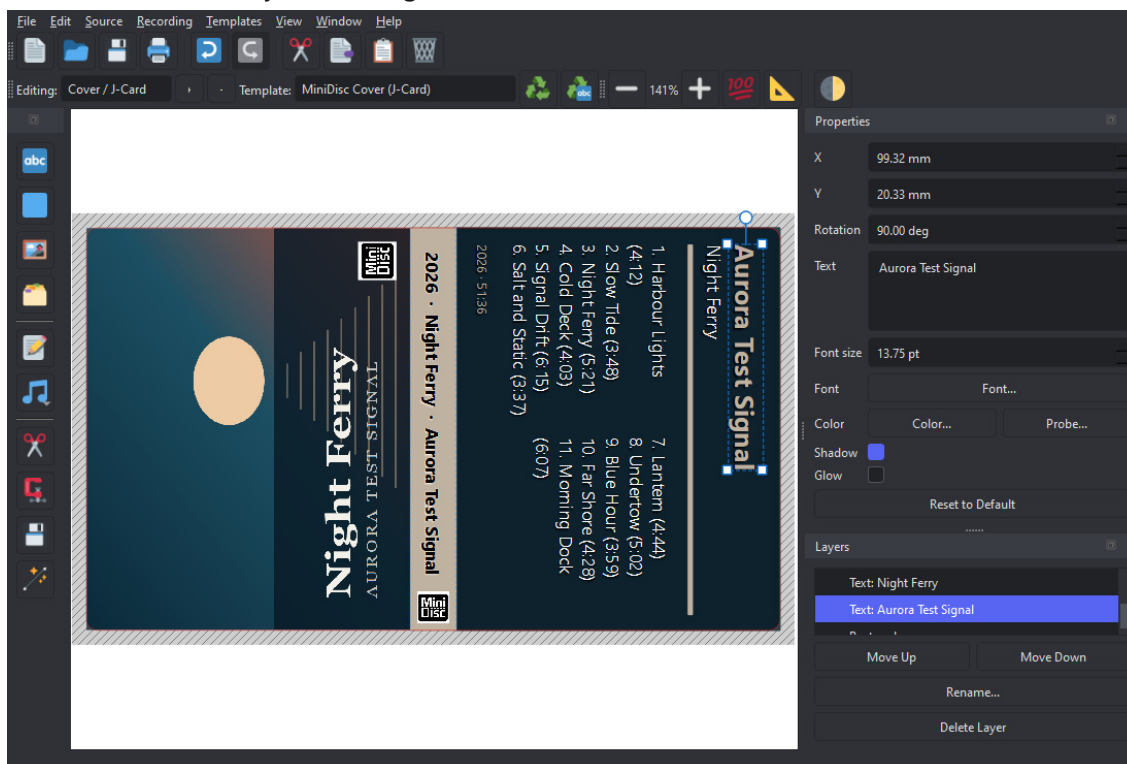

It builds each page **onto the template that page already has** -- it does not change your choice of shape. A page using one of your own templates is left alone entirely: the automatic layout only knows the built-in shapes, and a template you saved yourself may already have exactly what you wanted on it. Fill in album and artist in **Metadata...** first - that is what it searches by. If there is no cover art yet it looks one up before starting.

It **replaces the contents of every page it builds** and resets the undo history, so it asks for confirmation first. The metadata itself is left alone.

What it builds

The disc label: the full-face template, the cover art stretched across it and then cropped to the cut outline, and the MiniDisc logo on the shutter sticker. The insertion-orientation triangle and its label stay on top of the artwork rather than being buried under it.

That mark also **changes colour to suit the cover**: black or white, whichever stays readable against the top of that particular sleeve. Left at its default black it was still there over a dark full-bleed cover, just invisible, which looks exactly like having lost it.

7. The J-card, with every colour taken from the cover itself

The J-card, in three panels:

- **Front** - the cover art, turned a quarter turn so its top edge runs down the left side of the card, filling the panel, with a small MiniDisc logo in the corner.
- **Spine** - a band in an accent colour picked out of the cover, carrying the year, album and artist turned to read down it.

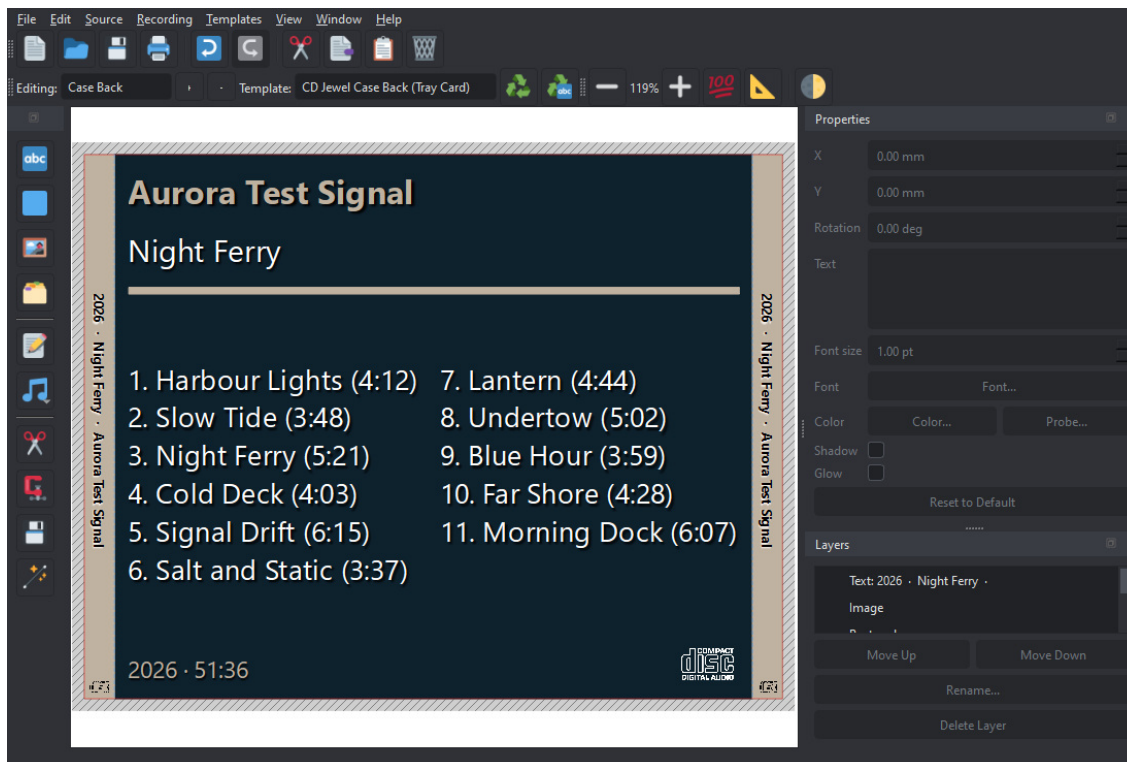

- **Back** - the cover's most common colour, with the numbered track list, split into two columns once the list gets long, and the running time at the foot.

The front and back are turned in *opposite* directions on purpose: the card wraps around the case, so the back ends up the other way up.

Everything it produces is ordinary layers. Move them, restyle them, delete them - it is a first draft, not a finished design.

The case back, if there is one

A CD project with a case back gets that laid out too: the album and artist run down **both** side strips -- which side of a case is visible depends on how it was shelved -- with the track list on the panel between them, in the cover's own colours.

8. The tray card: a printed strip down each side of the case, the track list on the panel that sits behind the disc.

This page keeps whatever template you gave it -- as every page now does. It was the first one to work that way, because it only exists at all because you added it and chose its shape, and the layout has no business undoing that.

Clip Layers and Bake Layers

Clip Layers trims everything to the printable area: layers entirely outside it are removed, images that hang over the edge are cut back to it. The automatic disc layout uses this to trim the deliberately oversized cover down to the cut outline.

Bake Layers flattens the whole page into a single image, exactly as the PNG export would render it. Useful for locking a finished design; note that a baked layer's resolution is fixed for good, which is why it renders at a higher DPI than a normal export.

7. Printing and cutting

The two exports

The design leaves xD-Tools as two files that describe the same object in two ways.

Export	Contains	For
Export Print PNG...	Your artwork, at 300 DPI by default, clipped to the template outline - transparent outside it, including the chamfered and rounded-away corners.	Printing.
Export Cut SVG...	Only the cut and fold lines of the current page, in real physical units. No artwork.	The cutting machine.
Export Print PNG (Grayscale)...	The same artwork converted to grey, with a brightness/contrast dialog and a live preview first.	Mono printers.

The Cricut route

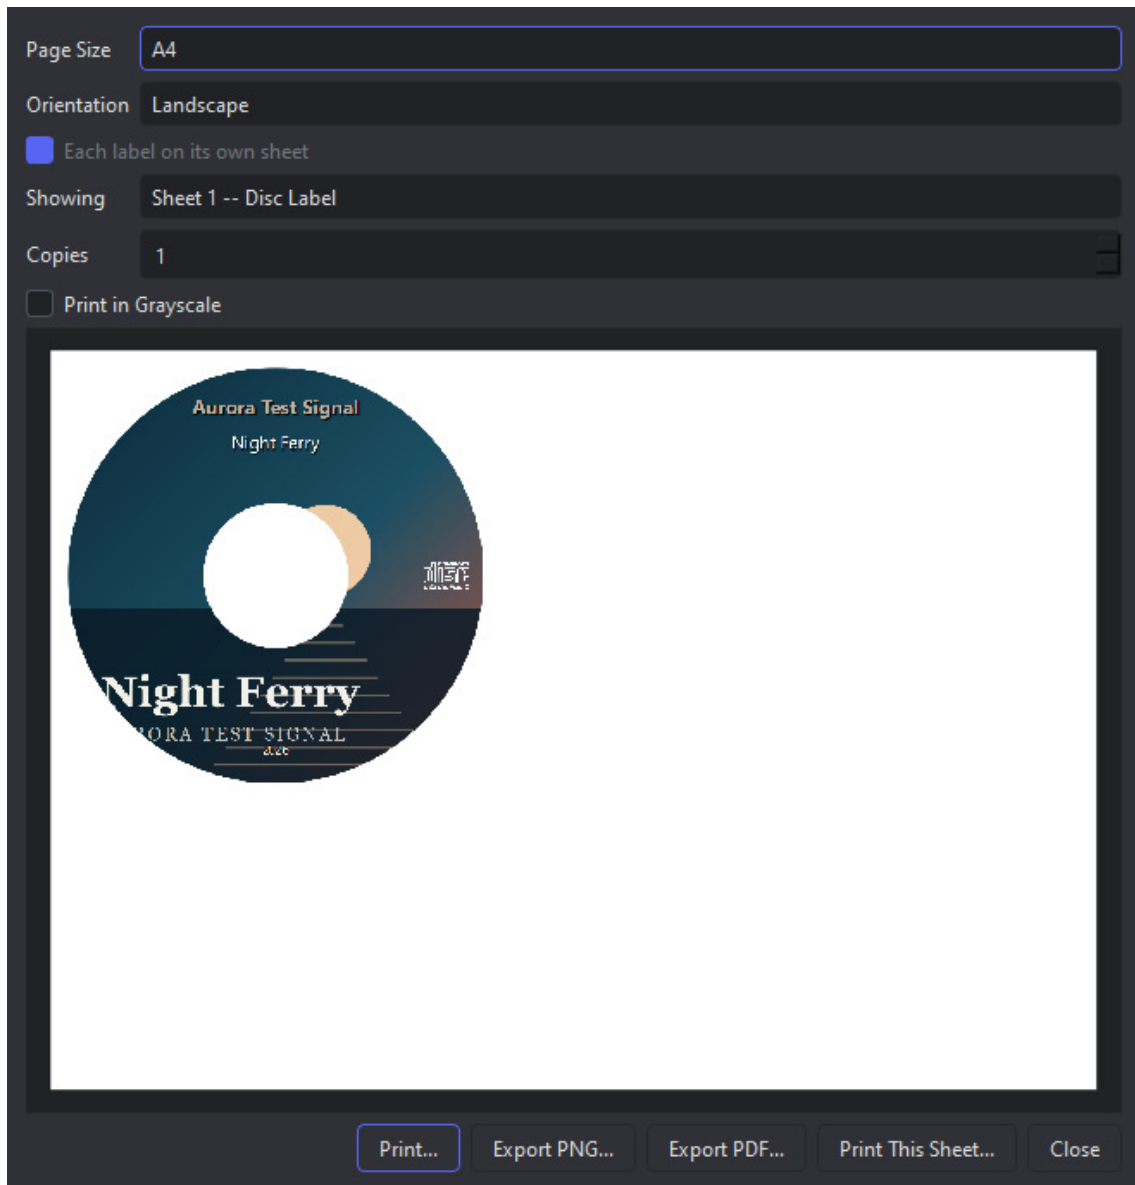

1. Export the PNG and print it on your sticker or card stock.
2. Import the SVG into Cricut Design Space.
3. Use **Print Then Cut**: the machine finds the printed sheet's registration and cuts the SVG's outline exactly onto it.

The SVG carries real millimetres, so nothing needs scaling by hand at the other end.

Orientation, and one label per sheet

The Print window has a **Page Size** and an **Orientation**. Landscape is not decoration: a CD's folded slim-case insert is 242mm wide, and no portrait sheet takes it upright - on a portrait A4 it can only be printed turned a quarter turn.

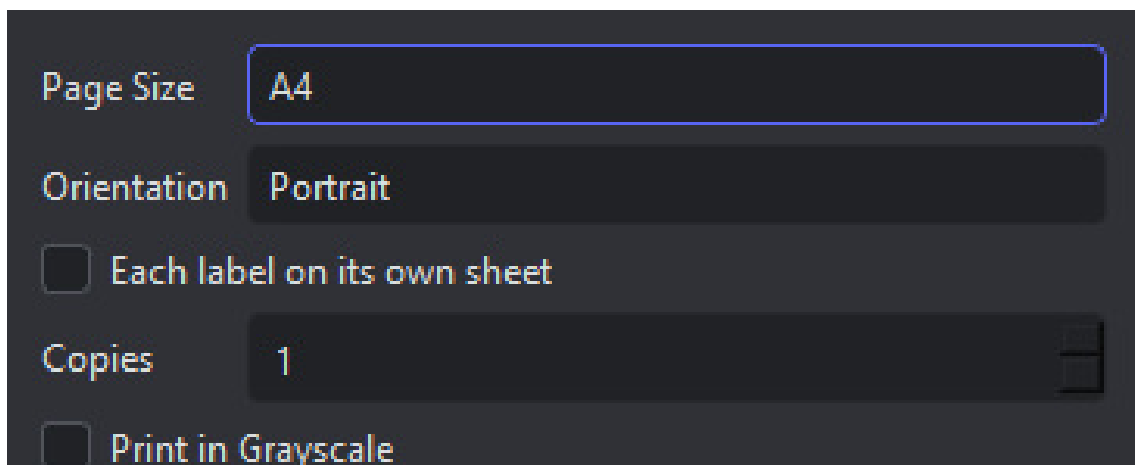

Each label on its own sheet does what it says, and for a CD project it is switched on for you. The reason is arithmetic rather than taste: a CD label (118mm) beside that insert (242mm) needs 363mm of a sheet that offers 287mm, so the two cannot share one however they are turned. With the option on, the preview shows one sheet at a time - the **Showing** box picks which - and printing, Export PDF and Export PNG all walk both. A PNG holds one page, so exporting two sheets writes two files, numbered.

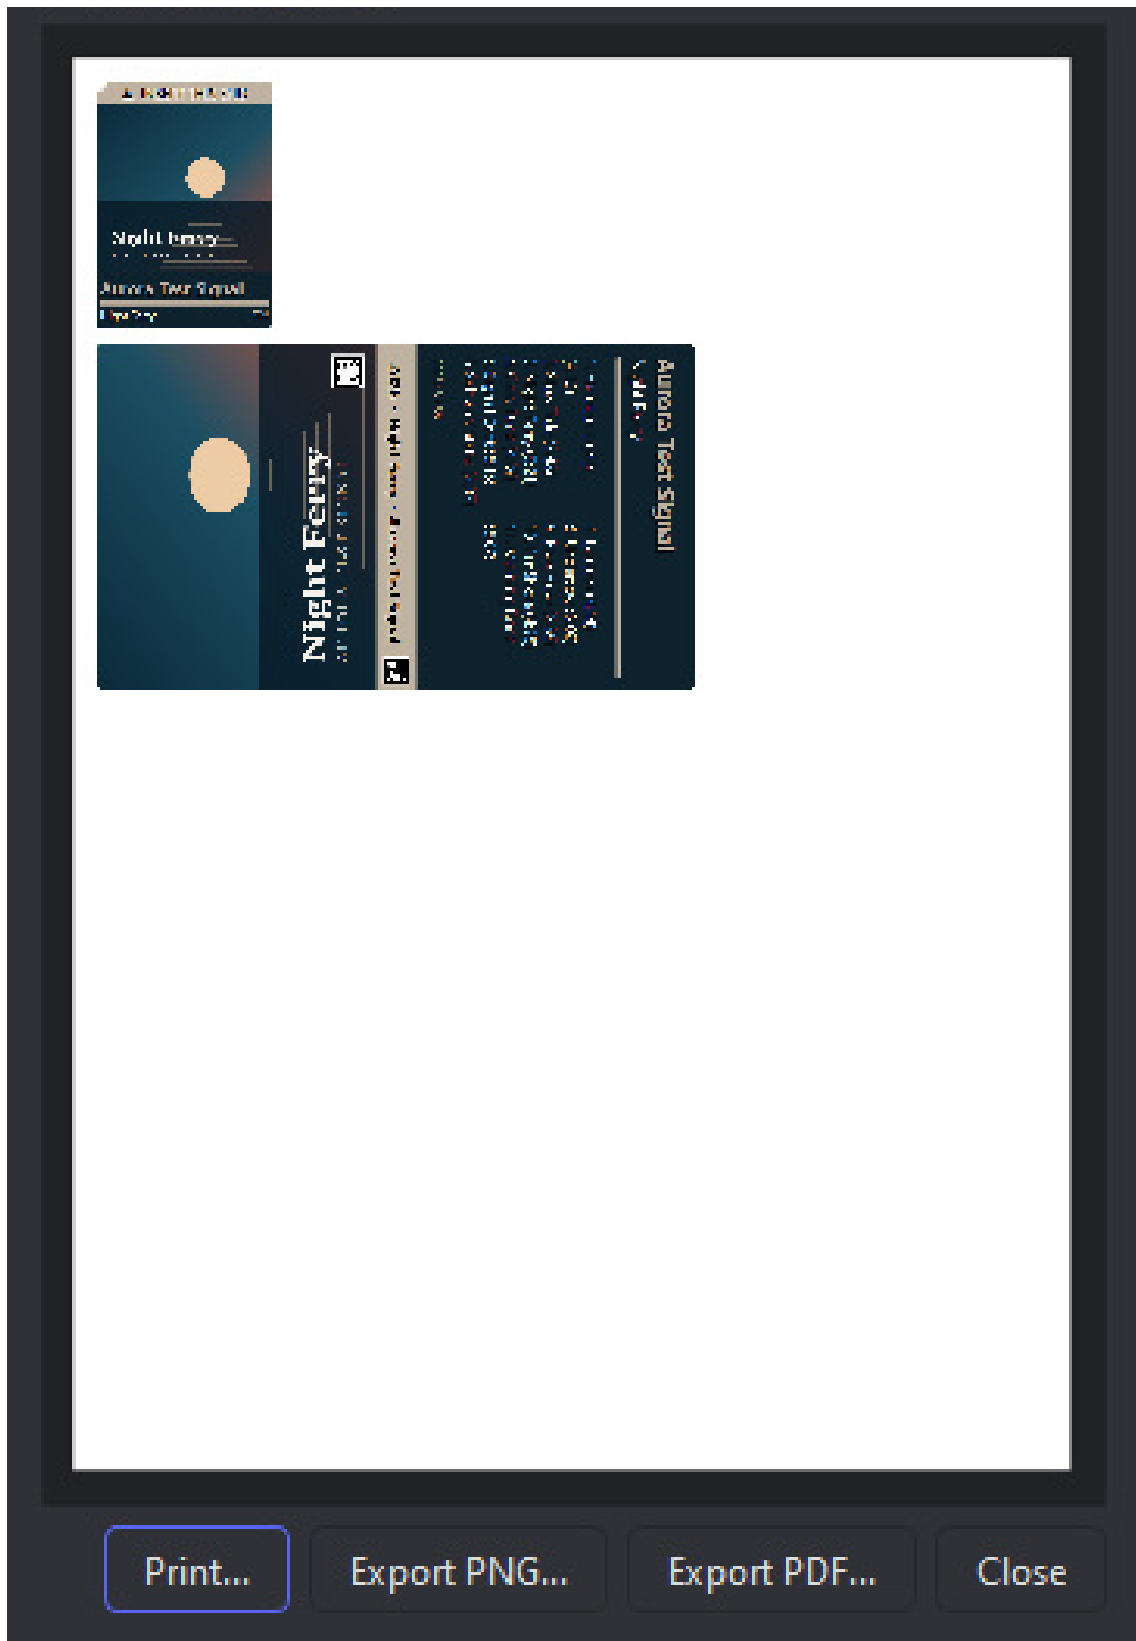

9. A CD project's print layout: the disc label on its own sheet, the folded insert on another.

Printing directly

File > Print... skips the export step: it lays several copies of both pages onto one sheet of A4 or Letter, auto-arranged into a grid you can then drag around by hand. Right-clicking a copy turns it 90 degrees, which is often what makes one more fit.

10. File > Print. The preview is the physical sheet.

From here you can send it to a real printer, or save exactly what is shown as a PDF or a PNG.

Multiprint..., on the startup screen, does the same thing across *different* projects - add artwork from several saved `.mdproj` files onto one sheet, so a stack of discs is one print run instead of six.

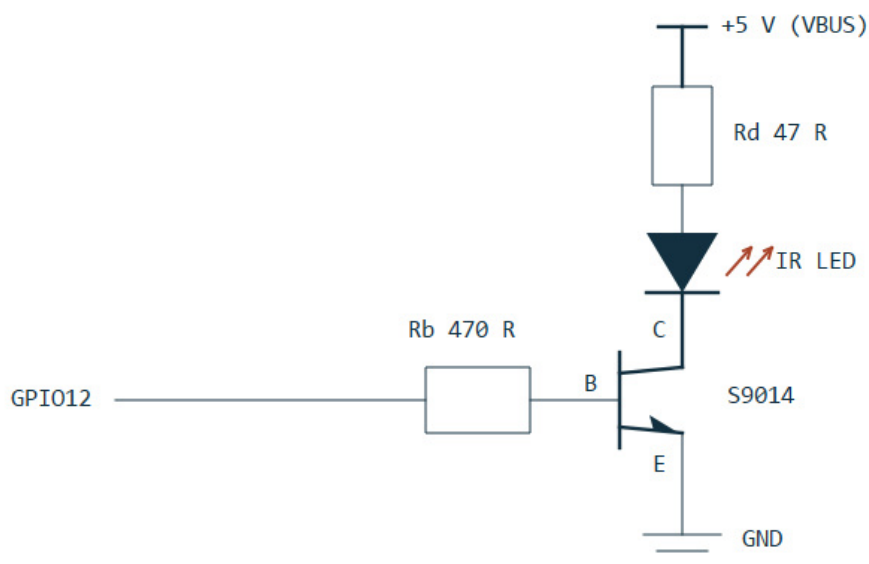

8. The MDRem adapter

MDRem is a Waveshare RP2040-Zero board with an infrared LED on it, running firmware that emulates a **Sony RM-D10P** - the keyboard remote Sony sold in the mid-nineties for typing titles onto MiniDiscs. It appears on the computer as an ordinary serial port.

The hardware

Pin	Role
GPIO12	Infrared output, into the transistor's base resistor.
GPIO13	Input, used only by the firmware's <code>SELFTEST</code> self-check.
GPIO16	The board's own RGB status LED.

The LED is driven by an NPN transistor as a low-side switch, because tens of milliamps cannot be pulled through a GPIO pin directly. Power comes from VBUS, not the 3.3 V regulator.

11. The output stage: S9014, $R_b = 470\text{ ohm}$, $R_d = 47\text{ ohm}$ (about 72 mA).

If the range is poor, look at R_d first. At 100 ohm (about 34 mA) the deck had to be within a centimetre or two and aimed precisely; at 47 ohm it works from a comfortable 20-30 cm. Do not go below about 33 ohm - 100 mA is the S9014's limit.

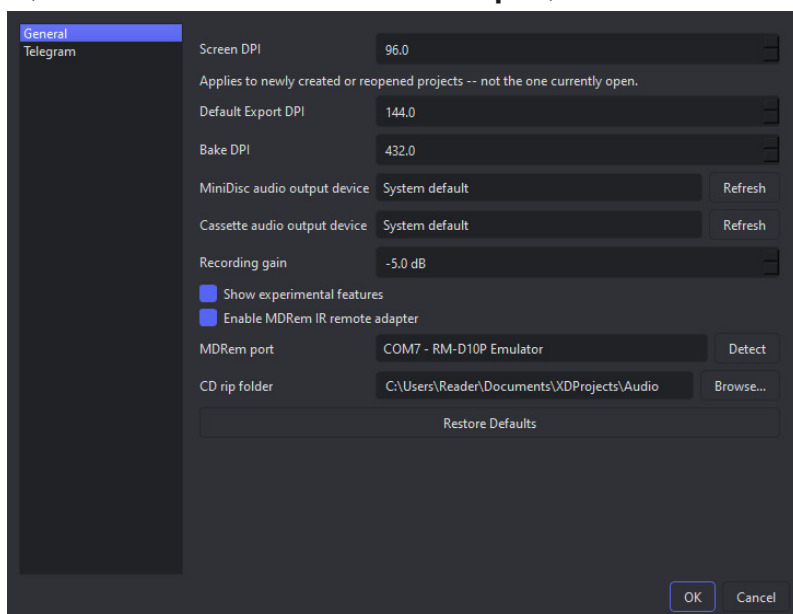

The status LED

Colour	Meaning
White	Starting up.
Green	Ready; the last command succeeded.
Blue	Transmitting infrared.

Red	The last command failed. Stays lit until something succeeds.
Purple	Hardware initialisation failed - the adapter is not working.

Turning it on in xD-Tools

Window > Settings..., tick **Enable MDRem IR remote adapter**, and choose the serial port.

12. *Window > Settings. The audio output devices are separate from the adapter - recording needs a device, not the infrared connection.*

Settings is one window with its groups listed down the left. **General** is everything here; **Telegram** is the bot account (its own chapter). Whichever group is on screen, **OK** saves all of them.

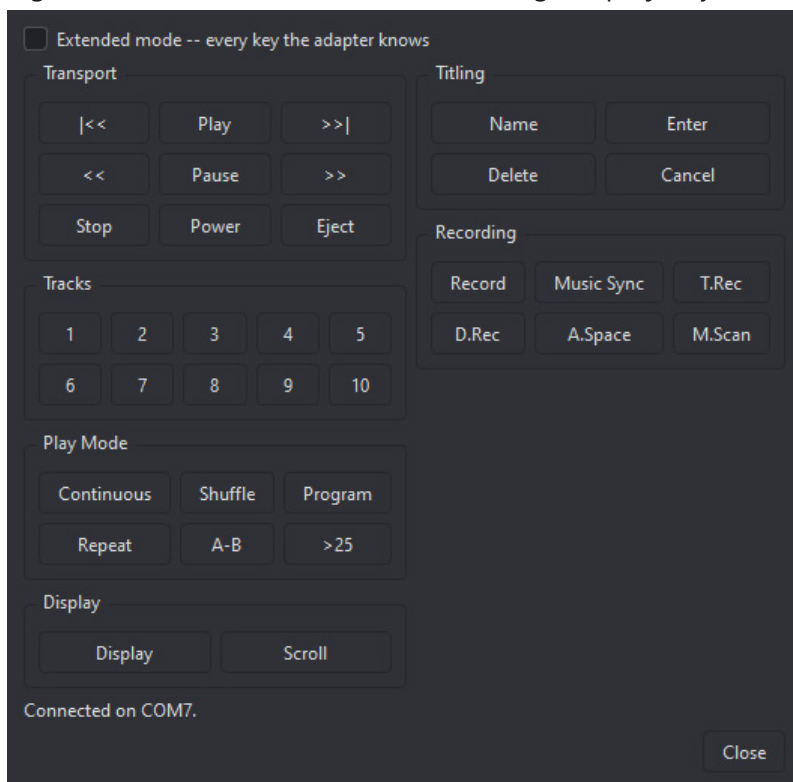

Detect asks every serial port on the machine whether an MDRem answers on it. It has to work that way: the board reports the USB ID `2E8A:0003`, which is also its own bootloader's and other WAVESHARE boards', so the only reliable identification is the device replying to a `PING`.

Three things appear once the checkbox is ticked: **Upload Tracklist** in the Metadata dialog, **Remote...** on the Window menu, and the MiniDisc entries in **Recording** - Record Folder to MiniDisc and Record from Rip/Download Folder to MiniDisc, both of which need the adapter to arm the deck. **Source > Rip Audio CD...** is not among them: ripping ends at files on disk and never touches the deck.

MiniDisc audio output device and **Cassette audio output device**, on the same page, are deliberately *not* tied to the checkbox - a cassette needs an output device whether or not the adapter is enabled, since nothing about recording onto one goes through MDRem at all. Each keeps its own choice, because a digital S/PDIF feed for one deck and an analogue line-out for the other are routinely different physical outputs. **Recording gain** (default -5 dB) backs the output level off a little before it leaves the computer, so a hot digital source has no chance to clip on the way in; it does not affect the audition player below.

9. The software remote

The software remote is a stand-in for the deck's own remote control, laid out the way a physical one is. It opens from either **Remote...** on the startup screen or **Window > Remote Control...** - the second exists because reaching for the remote should not mean closing the project you are working on.

13. The remote window. The status line reports what was sent, not what happened.

Group	Keys
Transport	Previous, Play, Next, scan back, Pause, scan forward, Stop, Power, Eject.
Tracks	1 to 10, selected directly - as many as the physical remote has keys for. 11 to 25 are in extended mode, below.
Play Mode	Continuous, Shuffle, Program, Repeat, A-B, >25.
Display	Display, Scroll.
Titling	Name, Enter, Delete, Cancel.
Recording	Record, Music Sync, T.Rec, D.Rec, A.Space, M.Scan.

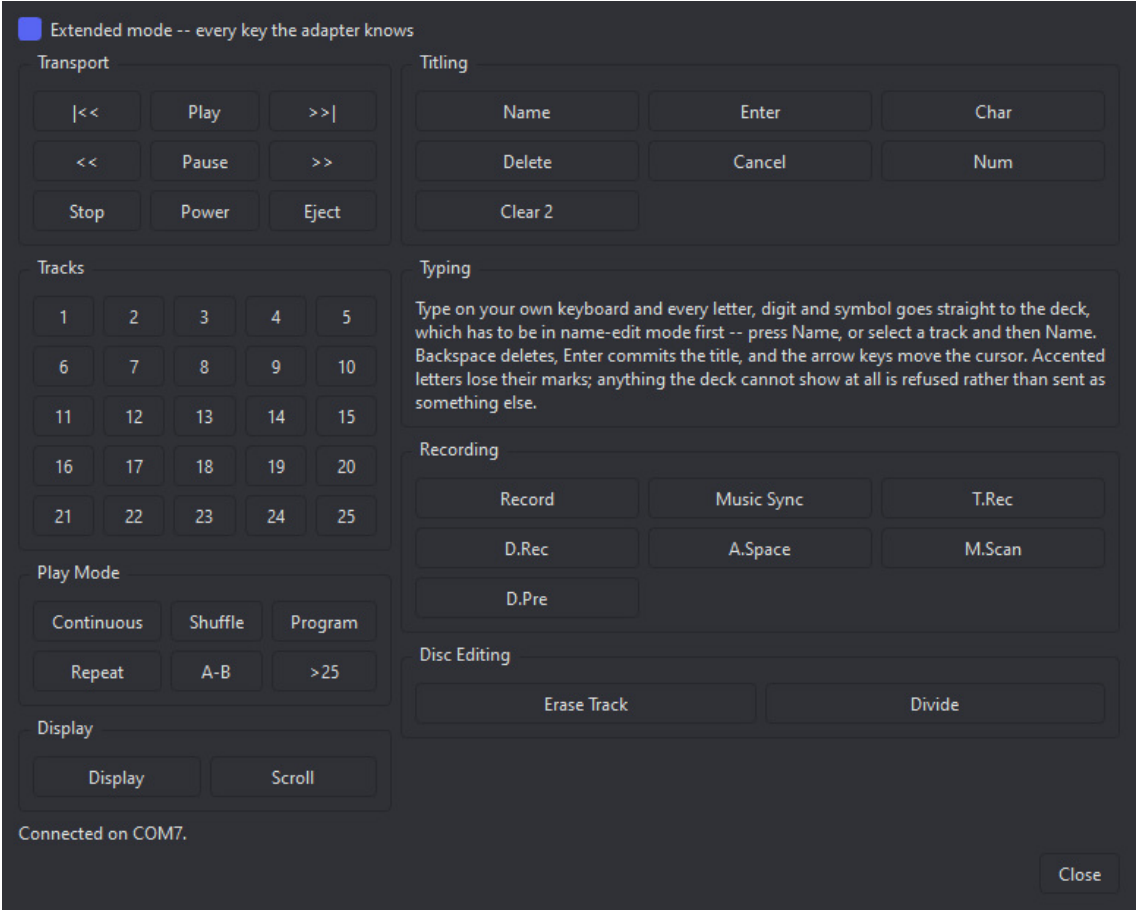

The Recording group is kept well away from the transport keys on purpose: on a real remote Record is a deliberate reach, and a mouse makes an accidental press far easier than a thumb does.

The status line says **Sent**, never **Done**. The deck cannot report back. If nothing happens, the most likely causes are aim and distance - see the troubleshooting chapter.

Record pressed while the deck is already recording adds a track mark. That is how the automatic recording splits a gapless album, and you can use it by hand the same way.

Extended mode

The window above is the physical remote, key for key. Tick **Extended mode** and it grows the rest of what the adapter can send - codes that exist, and were verified against a real deck, but that no key on the plastic remote reaches. The choice is remembered, so the window opens the way you left it.

14. Extended mode. Tracks up to 25, the deck's own character entry, and the two keys that edit the disc.

Added	What it is
Tracks 11-25	One code each, so they are one press like the first ten. Past 25 the number is typed rather than pressed, which is what titling does on its own.
Char, Num	The deck's own character entry - switching its character sets and picking with the jog dial. This app bypasses that by sending character codes directly, so these are here for completeness.
Clear 2	One of three keys the deck's code table calls Clear. It does nothing in name-edit mode, wherever the cursor is; it most likely clears a play program.
D.Pre	Recognised by the deck as a recording command. Which one of that group does what has never been told apart.
Erase Track, Divide	These edit the disc itself - erasing the current track, or splitting it in two.

Erase Track and Divide change what is on the disc. The deck asks on its own display first and does nothing until Enter, so Cancel backs out - but read the display before pressing Enter, because nothing here can undo it.

Typing on your own keyboard

The RM-D10P this stands in for is a keyboard, and in extended mode so is this window: with it open, every letter, digit and symbol you type goes straight to the deck. There is no text box and no on-screen keyboard on purpose - the remote has keys because a deck has none, and the computer running this already has better ones.

Put the deck into name-edit mode first: press **Name**, or select a track and then **Name**. Then type.

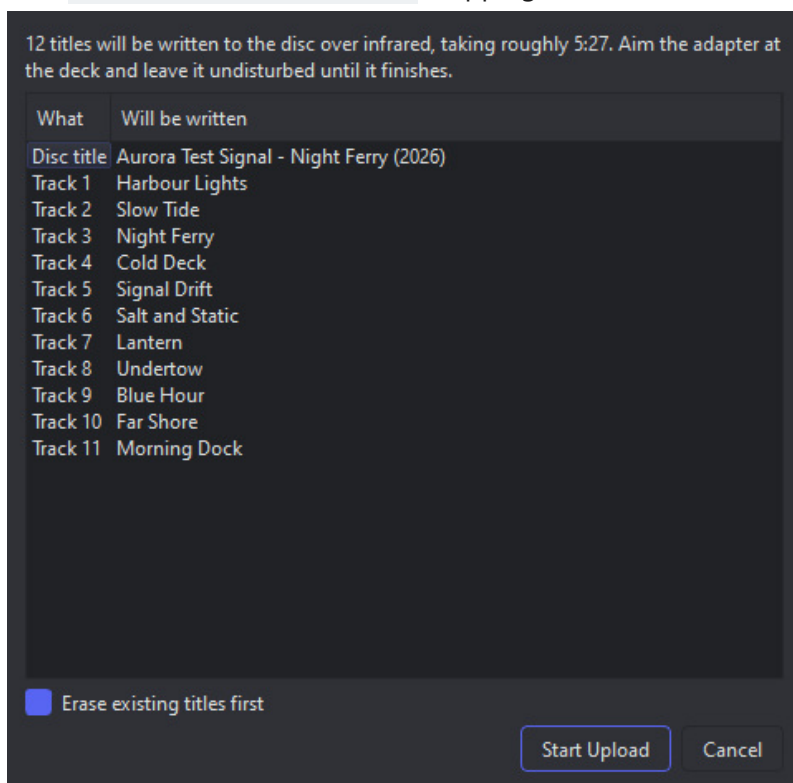

Backspace deletes, **Enter** commits the title, and the **arrow keys** move the cursor along the field.

Accented letters lose their marks on the way, exactly as they do when titles are written from a project - ã arrives as 1. A character with no Latin equivalent at all is refused and said so on the status line, rather than being sent as something else.

Typing is paced to what the deck can take - about three or four keypresses a second. Type faster than that and it keeps up by waiting, because two presses arriving too close together are read as one key held down.

10. Writing titles onto the disc

Metadata... > Upload Tracklist writes the disc title and every track name onto the MiniDisc itself. The disc title is assembled as `Artist - Album (Year)`, skipping whatever is not filled in.

15. Everything is shown before anything is written.

Before it starts

The list is exactly what will be written, already converted. Read it: this is the only chance to notice a title that came out wrong, because afterwards nothing can tell you what actually landed on the disc.

It is slow, and that is the deck

The deck accepts about three and a half keypresses per second, and every character is its own infrared frame. A full album takes three to four minutes. The original Sony remote was no faster - contemporary reviews complained about it. The point is that you type on a real keyboard and walk away.

Job	Roughly
One track title, on a disc with old titles to clear	about 25 s
One track title, on a freshly recorded disc	about 12 s
A whole album, clearing first	3 to 4 minutes

Erase existing titles first

Clearing the old title is the single slowest part of writing a new one and roughly doubles the total time. It is on by default because leaving it off over an existing title leaves the old text behind, with the new text running into it.

Turn it off on a disc you just recorded. There is nothing there to erase, and it very nearly halves the wait. The recording flow turns it off for you.

Because the old title cannot be read back, clearing deliberately overshoots: it sends more delete presses than the new title could possibly need. Extra deletes on an empty field cost nothing.

Titles are converted to plain ASCII

MiniDisc decks only display characters 0x20 to 0x7E. Accented letters lose their marks - Zazolc gesla jazn - and anything with no Latin equivalent at all is dropped. The dialog lists the dropped characters before writing anything.

Japanese titles do not work, even though MiniDisc is a Japanese format. The deck's own katakana is reachable only through its native entry method - the CHAR key plus the jog dial - which is a different input path entirely and takes ten seconds a character. Transliterate instead.

Eject when it finishes

A deck holds edited titles in volatile memory until the disc is ejected. Pull the power first and everything you just wrote is gone. The dialog offers to eject for you when it is done - say yes.

Tracks above 25

The remote itself has number keys only up to 25, but the adapter types a higher number in rather than pressing one key, so tracks 26 to 99 are written like any other. The deck's number field commits on the second digit, so a track past 99 cannot be selected at all - those titles are listed as skipped rather than silently dropped, and only an LP4 disc ever gets that long.

11. Recording an album to MiniDisc

Recording to MiniDisc is one shared window reached from two starting points - **Record Folder to MiniDisc...** for an album you point at yourself, and **Record from Rip/Download Folder to MiniDisc...** for whatever a CD rip or a Telegram download has left in the audio folder. This chapter covers what happens once you are in it, whichever door got you there: it arms the deck, plays the album through xD-Tools' own audio engine, watches it to the end, writes the titles, and lays out both labels from the album's own artwork.

This needs the MDRem adapter, and the entries only appear once it is enabled in Window > Settings... The adapter is what puts the deck into record and what marks the tracks. Without one, recording means pressing record on the deck yourself and letting its own LEVEL-SYNC decide where the tracks begin - xD-Tools has no part in that.

Setting up

1. Connect the computer's **S/PDIF** output - optical or coaxial - to the deck's digital input. This carries the audio; the USB link carries only commands.
2. Choose that output in **Window > Settings... > MiniDisc audio output device** - see the MDRem chapter. Nothing needs configuring on the source files themselves.
3. Put a blank or erasable disc in the deck, tab closed, and set the recording mode (SP or LP2) **on the deck** - xD-Tools cannot read or change it.
4. Turn **LEVEL-SYNC off** on the deck. See below.
5. Aim the adapter at the deck's remote sensor and leave it there.

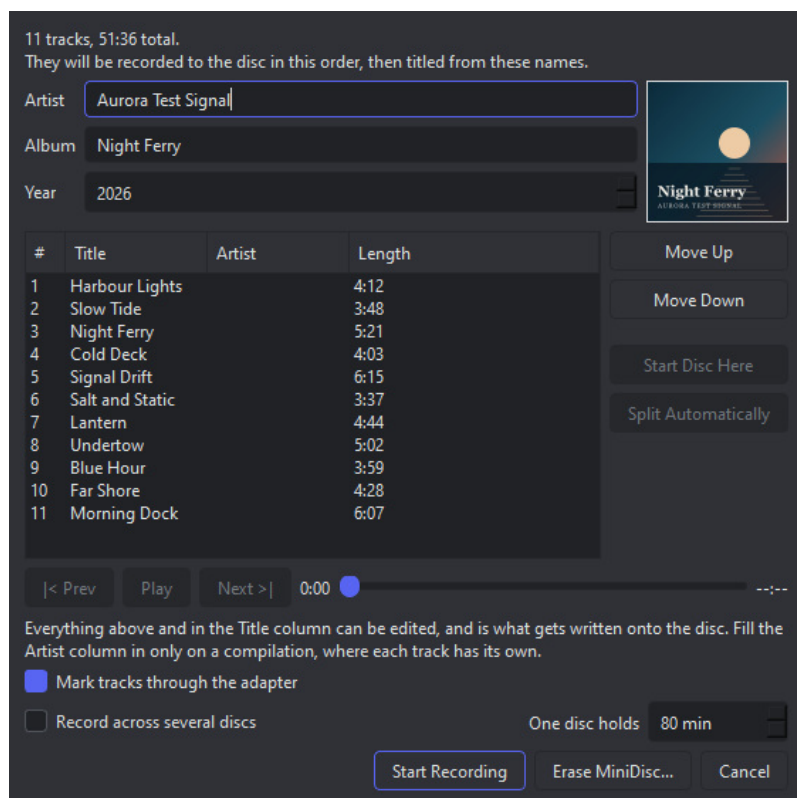

The format going into the deck

A MiniDisc is 44.1 kHz, 16-bit stereo, and the deck's digital input expects to be fed exactly that. xD-Tools converts every file automatically, whatever its own rate or bit depth - a 96 kHz or 24-bit download included - so there is nothing to set up on the source side. The conversion is not a plain truncation either: it resamples with the same high-quality resampler the CD-R burn path uses, and dithers the result down to 16 bits with a noise-shaped dither, rather than leaving that rounding to whatever happens to be downstream of the sound card.

Analogue instead, if you have to

The deck's **analogue** line inputs work too, and xD-Tools drives the recording exactly the same way - it presses the deck's keys, which does not depend on how the audio arrives. **The quality is considerably worse**, though, and unavoidably so: the sound leaves the sound card as analogue and is digitised again by the deck, so it picks up two extra conversions and whatever noise the card's output stage adds, before ATRAC has even started. Use S/PDIF whenever the deck has it.

Going analogue also means setting the deck's input selector to analogue and its recording level by hand - a digital input has neither to worry about.

16. The playlist as it will be recorded, in that order.

What the window shows

The album, artist and year the disc will be titled with, the cover art it will be labelled with, and the track list - all of it editable. **This is the last place to correct any of it:** once the recording has run, those titles are already on the disc. The cover is looked up as the window opens rather than when the album ends, for the same reason. Everything freezes the moment recording starts.

Fill in the **Artist** column only when the tracks are by different performers. On an ordinary album it stays empty; on a compilation it is what tells xD-Tools the disc is one.

Listening before you commit

Select a track and the small transport bar under the list lets you **Play/Pause** it through the computer's own default output - not the recording sink above, so it works even when that is a digital feed with nothing else listening on it. Drag the slider to check a particular passage, and **Prev/Next** step through the album without going back to the list. It is there to catch a wrong file or a bad edit before forty minutes goes down onto the disc, not to audition the whole album end to end.

The player switches off while a recording is actually running - it plays through the computer's default output, which may be the very device feeding the deck.

What happens

1. xD-Tools shows the playlist and its total time, and warns if it will not fit on an 80-minute disc in SP.
2. It decodes, resamples and dithers the whole disc up front - see above - applying the **Recording gain** setting to leave the deck some headroom.
3. It tells the deck to start recording, then **asks you to confirm the deck really is in record-pause**. It cannot check, and getting this wrong means playing a whole album into a deck that is not recording and finding out forty minutes later.
4. It releases the pause, and a moment later starts playback - in that order, so the deck is already running when the first note arrives.

5. Recording runs. You can watch which track is going down and how much is left. Stop stops both ends.
6. When the album ends it offers to write the titles, taken from the playlist itself.
7. Finally the album, artist, year and track list become the project's metadata, cover art is looked up, and **the project's pages lay themselves out**, each on the template it already has.

That last step **replaces whatever was on the pages it builds**. After a recording it does not ask - you have just sat through several prompts and watched an album go down in real time, and one more would be noise.

Track marks: the important part

A CD player tells the deck where the tracks are, in the S/PDIF subcode. **A computer does not**. Left to itself the deck falls back on LEVEL-SYNC: it starts a new track whenever the sound drops to silence and comes back.

That fails on any album where one song runs into the next. Two songs with no gap between them are recorded as one long track, and no amount of editing afterwards makes that pleasant.

So xD-Tools sends a track mark itself, at the exact sample its own player crosses from one track's audio into the next - that is the **Mark tracks through the adapter** checkbox, and it should stay ticked.

Turn LEVEL-SYNC off on the deck when you use it. Running both marks the same boundary twice, a fraction of a second apart, and leaves a sliver of a track stranded between them. They fight; they do not co-operate.

Recording mode and length

An MD holds 80 minutes in SP. xD-Tools warns when the playlist is longer than that, but it can only warn - LP2 and LP4 have to be set on the deck itself, and there is no way to read back which mode it is in.

An album that takes more than one disc

A double album does not fit on a MiniDisc, and a MiniDisc cannot be turned over the way a cassette can. **Record across several discs** records it a disc at a time instead: one disc, its titles, eject, the next blank, and so on.

Tick it and the track list gains a **Disc** column showing where the album is cut, with a line underneath saying how full each disc ends up. **One disc holds** is the number that decides it - 80 minutes in SP, 160 in LP2. xD-Tools cannot read which mode the deck is in, so that number is yours to state.

1. Each disc is recorded exactly as a single one is: armed, confirmed, played, marked.
2. **Two seconds after the last track of that disc, the titles go out by themselves** - no question, no button. Nobody sits through forty minutes of album, and a MiniDisc keeps an edited title list in memory only until the disc is ejected.
3. The disc is ejected, and xD-Tools asks you to put the next blank one in.
4. The last disc finishes the same way and the run ends.

Each disc is titled with the album's name and **[1/2], [2/2]** after it. Two discs of one album titled identically are two discs nobody can tell apart on a shelf. The tracks on each are numbered from one, which is how the deck numbers them anyway.

The preview that Upload Tracklist normally shows is given up here - there is nobody at the machine to read it. That is why every title, and every character the deck cannot show, is on screen in this window **before** the first note plays.

Where the album is cut, and in what order

xD-Tools puts the playlist into the album's own order as the window opens: by disc number first, then by track number, both read from the files themselves. A two-disc set kept as one folder arrives interleaved, because both discs number their tracks from one - this is what puts it right before anything plays.

If the files say how many discs there are, the splits are placed where they say and the option is ticked for you. Otherwise the album is divided as evenly as its running order allows, into the fewest discs that fit.

- **Move Up / Move Down** change the order the album is recorded in.
- **Start Disc Here** makes the selected track the first of a new disc; pressed again on the same track, it takes that split away.
- **Split Automatically** throws away the splits you placed and works them out again.

12. Ripping a CD

Source > Rip Audio CD... copies an audio CD to files. It reads the disc, works out what album it is, extracts every track, and stops there - it offers to bring the album's title and track list into the project, tells you where the files went, and that is the end of it.

Recording those files is a separate step you start yourself, from **Recording > Record from Rip/Download Folder to {medium}...** - the ordinary recording window the previous chapter describes, with the same arming, the same track marks and the same titling. The two used to be one unbroken run, which meant a copy could only be had by starting a recording; a rip is worth having on its own, and the disc is in the drive now whether or not the deck is free.

Ripping needs no MDRem adapter and no particular kind of project, which is why it sits in the Source menu with nothing hidden or renamed for the medium. Only the recording that may follow needs the adapter, and only on a MiniDisc project.

Why it copies the disc first

A drive can play a CD directly, and letting a recording read it in real time would be simpler. But then a scratch stumbled over at minute 31 lands directly on the MiniDisc, with nothing to fall back on - and a MiniDisc recording is not something you can patch afterwards.

Copying first moves every read error to a point where it costs a re-read and nothing else. xD-Tools uses **cdparanoia** for this, built precisely to keep working at a damaged disc until it gets the audio right, and **flac** to store the result. Both ship with xD-Tools; there is nothing to install.

17. The disc read, identified, and ready to copy.

Step by step

1. Put the CD in the drive and choose the drive from the list. **Refresh** looks again if you plugged one in after opening the window.
2. Press **Read Disc**. xD-Tools reads the table of contents and looks the disc up on MusicBrainz, which identifies it from the lengths of its tracks - a CD carries no text of its own.
3. Check what came back. If several pressings match, pick the right one from **Release**; the track titles and the cover art change with it.
4. Correct anything wrong. The titles are editable, and they are what gets written into the files and later onto the MiniDisc.
5. Press **Rip**. When the copy finishes, xD-Tools names the folder the files went into and asks whether to bring the album's title and track list into the project.

A disc that is not in MusicBrainz - anything home-burned, and plenty of obscure releases - simply comes back with numbered placeholder titles for you to type over. Nothing else about the process changes.

How long it takes

Expect roughly **fifteen minutes for a full album**, about three times faster than playing it. That is cdparanoia being careful, and it is the price of the error correction that made copying worth doing in the first place. The recording itself then takes as long as the album does, because it happens in real time.

When the disc is a compilation

A mixtape is not an album, and treating it like one goes wrong in visible ways: the disc gets named after whichever track happened to be first, the J-card credits one performer for twelve, and a cover art search returns some unrelated record's sleeve.

So xD-Tools checks. If most of the tracks cannot be attributed to a single artist, it credits the disc to **Various Artists**, names it **Mixtape** unless the release has a name of its own, prints each performer beside their track on the J-card, and **draws a cover from the track list** instead of looking one up.

Fill in the **Artist** column yourself when you know a disc is a compilation and MusicBrainz did not say so - that column is what the check reads.

An album with a guest feature on one track is **not** a compilation, and is not treated as one. The test is whether most tracks belong to the same artist, not whether the credits vary at all.

The same applies to a folder of files recorded directly ("Recording a folder of files"): a folder of unrelated tracks is recognised the same way, with the same result.

Where the copied files go

Into **Documents\XDProjects\Audio** by default, one folder per album - the same folder Telegram bot downloads land in (its own chapter), since both are raw material for a recording rather than a music collection. It is created if it is not there, and **Window > Settings... > CD rip folder** can point it somewhere else.

Ripped files are **never deleted automatically**, by this or anything else in xD-Tools - not when a recording finishes, not to make room for a later rip. What accumulates there is yours to clear out by hand, whenever and however you like.

A set of several CDs

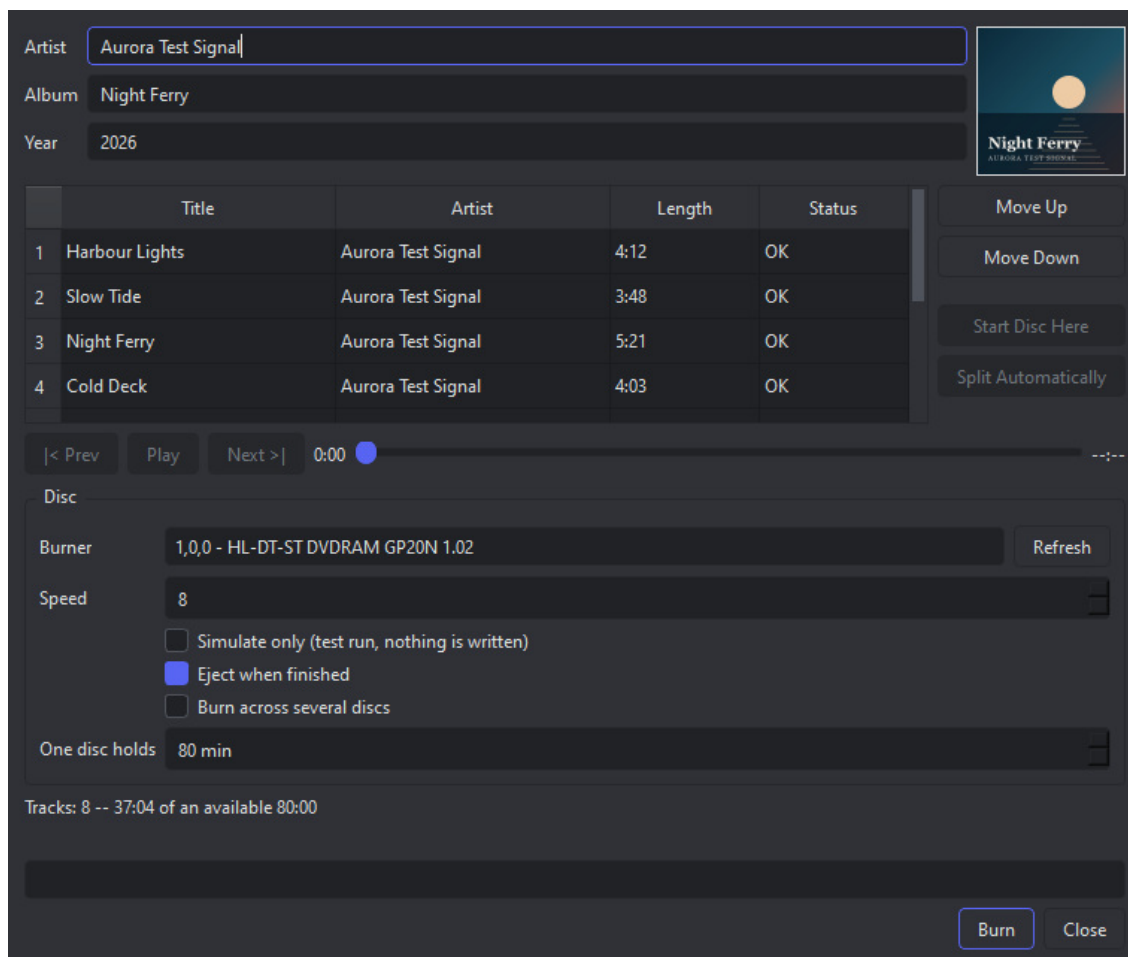

Rip several discs as one album copies a boxed set as one album rather than as two unrelated ones. Each disc is read, identified and ripped on its own, and xD-Tools then asks for the next.

- They all land in **one folder**, the one the first disc made. A later disc is often identified under a title of its own - "... [Disc 2]" - and a folder per disc would be two albums.
- The album, artist and year stay the ones from the first disc. The **titles** are each disc's own, which is what the lookup is for.
- Every file is tagged with the disc it came from, and carries that number in its name. That is what lets everything afterwards - the playlist, a recording, a burn - put the set back in its own order.
- When you stop adding discs, the recording that follows records the whole set at once.

You can stop after any disc: the question offers to carry on or to keep what has been ripped so far.

13. Burning an audio CD

On a CD project, **Recording > Record Folder to CD...** - the same entry "Recording a folder of files" covers for MiniDisc and cassette - writes a real Red Book audio CD-R instead: the kind any CD player will play, from a folder of files you already have. No infrared adapter is involved: this is the drive's job, so it stays available even with MDRem switched off.

18. The burn window: what will be written, and what it will be called.

What the window shows

The album's name, artist and year, an editable title and artist per track, and a cover you can click to replace - the same window the recording flow uses, and the same rule: **what is on screen when you press Burn is what gets written**, both onto the disc as CD-Text and into the project you design the label from.

The line under the track list gives the album's length against what the disc holds. The **Status** column is the part worth reading before you press anything.

Select a track and the transport bar under the list plays it through the computer's own default output, with a seek slider and Prev/Next - the same audition player the MiniDisc and cassette recording windows have, worth a listen before a disc that cannot be rewritten gets committed.

Why a track can refuse to be burned

A CD holds 44.1 kHz, 16-bit, stereo audio and nothing else. Two Red Book rules can stop a burn outright, and the window says so per track rather than letting you find out on playback:

- a track shorter than **four seconds**, which some players will not play;
- more than **99 tracks**, or an album longer than the disc.

A file that is merely at the wrong rate is not a refusal. A 48 kHz / 24-bit download - which is what most of them are - says "will be converted to 44100 Hz / 16-bit" and is resampled and dithered on the way to the disc by xD-Tools' own audio engine. The conversion happens in a scratch folder; your own files are never touched.

Titles on the disc: CD-Text

The album and track names are written onto the CD as CD-Text, which players that support it will show. It carries plain ASCII, so accented letters lose their marks the same way MiniDisc titles do - and anything with no equivalent at all is listed in the window **before** you burn, rather than quietly dropped.

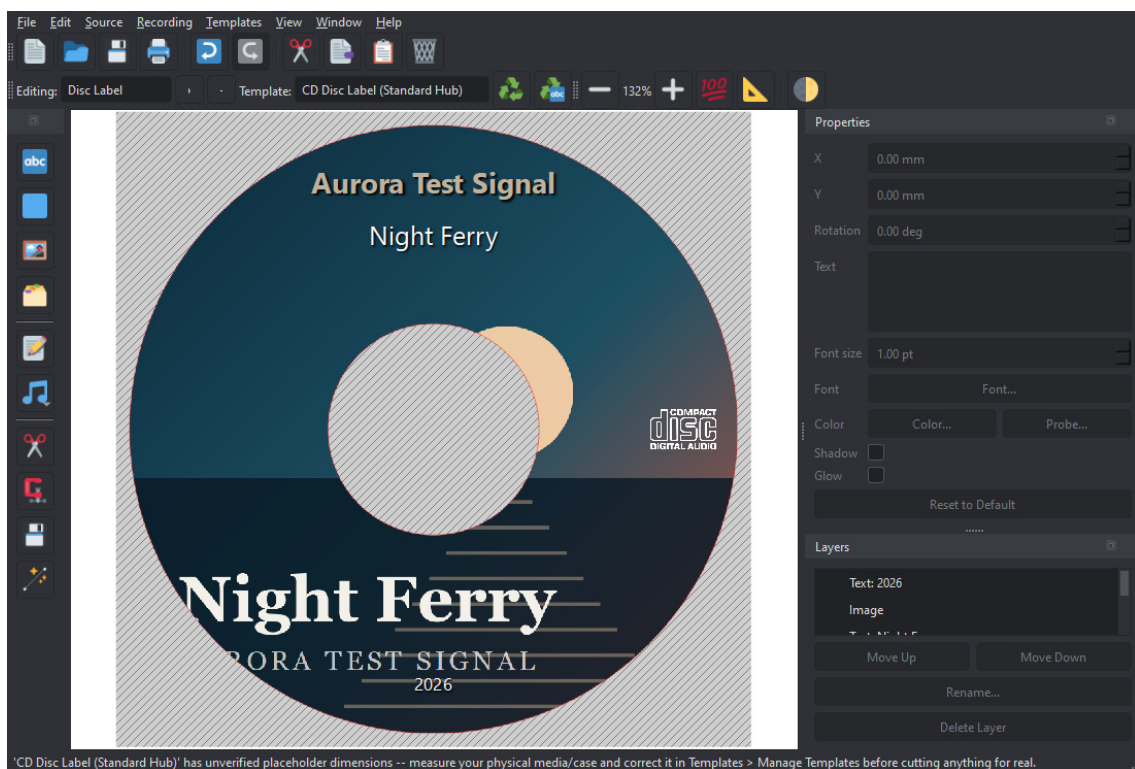

Simulate first, if you like

Simulate only runs the whole sequence with the laser off. It takes as long as a real burn and proves the drive, the speed and the files, without spending a disc. Worth doing once on a new drive.

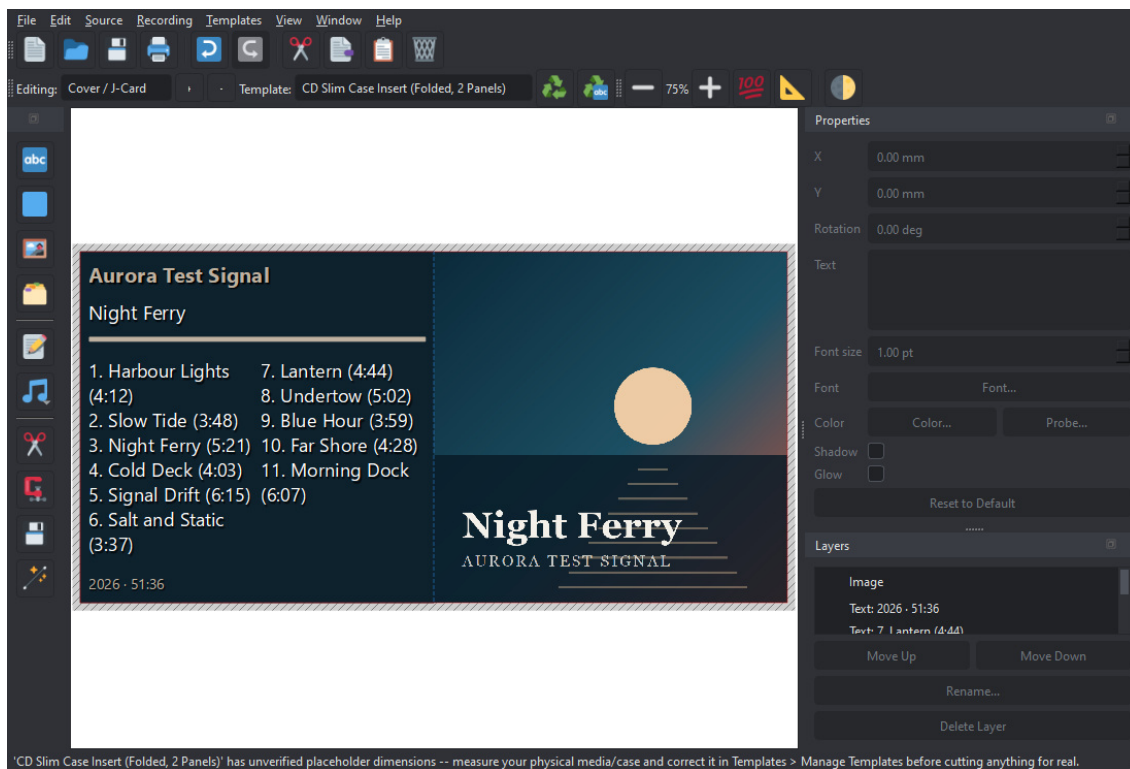

A CD-R cannot be rewritten. Once writing starts, the disc is either finished or wasted - which is why the window asks before starting, and asks again if you press Stop while the laser is on. Stopping during the earlier "Preparing audio" stage costs nothing at all.

The label, afterwards

When the burn finishes, the album's details are offered to the open project if it is a CD one. Say yes and the Tools panel's automatic layout has everything it needs: the cover, the artist, the year and the track list.

19. The disc label: the cover lightened across the ring, with the hub cut out and the Digital Audio mark at the foot.

20. The folded slim-case insert: cover on the right panel, track list on the left. Folded down the middle, the left half shows through the back of the case.

What you need

- A CD writer. It is found by asking cdrecord, not by guessing - if the **Burner** box is empty, check the drive is connected and press **Refresh**.
- A blank CD-R. A disc that already holds something cannot take a fresh burn.
- Nothing else: cdrecord is bundled on Windows, and the resampling is xD-Tools' own.

An album that takes more than one disc

Burn across several discs writes a long album onto as many CD-Rs as it needs. **One disc holds** is what that depends on: 80 minutes on an ordinary blank, 74 on an older one.

The track list gains a **Disc** column showing where the album is cut, and the summary gives each disc's own length. Every disc is measured against the disc it goes on - the album overrunning is the point - so the Burn button stays off until each of them fits.

1. Each disc is written and then ejected, whatever **Eject when finished** says: the tray has to open for the next blank to go in.
2. xD-Tools asks you to put that blank in, and writes the next disc.
3. You can stop at any of those questions; the discs already written are finished.

Each disc's CD-Text carries the album's name with **[1/2]**, **[2/2]** after it, for the same reason MiniDisc titles do.

Where the cut falls comes from the files when they say - a ripped boxed set carries its disc numbers, and those are honoured rather than balanced over. The same four buttons as the recording window are here too: **Move Up**, **Move Down**, **Start Disc Here** and **Split Automatically**.

14. Recording a folder of files

Recording > Record Folder to {medium}... records an album you already have on disk - onto a MiniDisc, a cassette, or a CD-R, whichever the open project is for. Point it at the folder it is in and xD-Tools reads the files' own tags directly, then hands over to the recording flow you already know from the previous chapters - the same arming, the same track marks, the same titling (or, on a CD project, straight to burning).

Recording needs the MDRem adapter on a MiniDisc project, and the entry only appears once it is enabled. Reading a folder does not need one; a cassette or a CD-R needs no adapter at all, on this entry or any other.

Folder: Browse...

Artist:

Album:

Year:

#	Title	Artist	Length
1	Harbour Lights		4:12
2	Slow Tide		3:48
3	Night Ferry		5:21
4	Cold Deck		4:03
5	Signal Drift		6:15
6	Salt and Static		3:37
7	Lantern		4:44
8	Undertow		5:02
9	Blue Hour		3:59
10	Far Shore		4:28
11	Morning Dock		6:07

The tracks are recorded in the order shown, which comes from the filenames. Titles come from the files' own tags; a file with no title tag is recorded under its filename.

Check the album below, then record.

21. The folder read, and what xD-Tools made of the files' own tags.

Step by step

1. Press **Browse...** and choose the folder the album is in. Its files are read immediately - choosing the folder is the decision, so there is nothing further to confirm. FLAC and WAV are recognised; anything that is not one of those - artwork, a cue sheet, a log - is ignored.
2. Check the order. It comes from the filenames, compared so that 10 follows 9 rather than 1. If it is wrong, the filenames are what to fix.

3. Check the album and artist. They are guessed from the folder's own name to start with, and whatever the files are tagged with replaces that guess as soon as the tracks are read. Type over either if both are wrong.
4. Look at what came back: the titles read out of each file's own tags, and the cover art - searched for first, and taken from inside a FLAC file itself if the search found nothing good.
5. Press **Record**.

Where the titles come from

From the files' own tags, read directly - the same reader a recording itself uses to decode them, so nothing here can disagree with what actually plays. A file with no title tag is recorded under its filename: the honest answer, and usually a usable one.

The album and artist shown in this window are what gets written onto the disc and onto the label, so a correction is worth making before you press the button. Nothing is ever written back into your files.

A subfolder per disc

A folder with tracks in it *is* the album, and its subfolders are left alone - a scans or bonus directory does not join the running order. Only when the folder itself holds no audio at all does xD-Tools look inside, which is what makes a two-disc album kept as `CD1` and `CD2` come out in disc order.

15. Recording a cassette

Record Folder to Cassette... and **Record from Rip/Download Folder to Cassette...** - the same entry points the MiniDisc chapter covers - lead here instead on a cassette project, and record an album onto a compact cassette one side at a time. It is the odd one out among the recording flows, and in a way that decides everything about it: **the deck is yours to operate**. There is no adapter for a tape deck and no cable that presses its buttons, so xD-Tools plays the right tracks at the right moment and tells you, in as many words, what to press and when.

This needs **no MDRem adapter at all** - just an output device chosen in Window > Settings... > Cassette audio output device (its own setting, independent of MiniDisc's). The entries appear whenever the open project is a cassette one, whether or not the adapter is switched on.

11 tracks, 51:36 total.
It will be recorded in this order, in two sides, through the deck's line inputs.

< Prev Play Next > 0:00

Side A: 6 tracks, 27:26 · Side B: 5 tracks, 24:30

Side A

Press RECORD and PAUSE together on side A (record-pause -- armed, but not yet moving), set its input to the line it is fed from, then press the button below. Once the tracks are ready you will be told to release Pause; the first 10 seconds after that are recorded silent, so the music clears the leader tape.

22. The split, the tape it was worked out for, and the instruction waiting to be acted on.

Choosing the tape

A stated length is both sides together: a C60 is thirty minutes a side, not sixty. Pick the cassette you actually have from the **Cassette** box and the album is split again as you do - the Side column in the track list, and the summary underneath it, both follow immediately.

The shortest tape the album fits is pre-selected when the window opens. That is a suggestion about the album, not about your shelf: change it to whatever is in the box.

Where the tape is turned over

xD-Tools never rearranges the running order. The only choice is which track the break falls after, and every possible break is tried: the one that leaves the two sides closest in length wins, among those that fit. Filling side A to the brim and leaving side B half empty saves no tape at all - the cassette is the same length either way - so there is nothing to be gained by it.

If nothing fits, the least-overflowing break is used anyway and the window says by how much. Running a few seconds into the run-out is your call to make, exactly as an album longer than a MiniDisc's eighty minutes is.

Tracks with no running time cannot be weighed, so the album is split down the middle by count and the window says so. Check that against the tape before you start.

The ten seconds of silence

Every side of a cassette begins with leader tape - a few inches of plain plastic spliced on to take the wear of being wound around the hub. It is not magnetic, so nothing recorded onto it survives. xD-Tools therefore records **ten seconds of silence** at the start of each side before the music begins, and those ten seconds come out of what that side holds.

Step by step, per side

1. Check the album, the artist, the year and the cover - they are what the labels will be printed from, and they freeze the moment recording starts.
2. Put the cassette in, wound to the start of the side. Press **RECORD and PAUSE together** - record-pause, armed but not yet moving - set its input to the line xD-Tools' own recording is fed through, and set the level.
3. Press the button below the track list. xD-Tools decodes the whole side up front, with a status line to show it is working rather than stuck.
4. A dialog tells you to **release Pause now** - the deck should start rolling. That click is the only confirmation there is that it really did - nothing here can see it - and it is also the moment the ten seconds of silence below start counting from, so releasing Pause promptly is what keeps the silence and the leader tape lined up.
5. Ten seconds of silence run down while the leader passes, then the side plays. xD-Tools' own player stops the instant the side's last track ends, rather than being caught afterwards - which is what keeps the first second of the next side off the end of this one.
6. Stop the deck, take the cassette out and turn it over, press **RECORD and PAUSE** again, and press the button for side B - the same release-Pause dialog waits for you there too.

Stop stops xD-Tools' own playback and says so - it cannot stop the deck, which will happily go on recording silence. That is the one thing only you can do.

Listening before you commit

The same audition player the MiniDisc and CD-burn windows have sits under the track list here too:

select a track, **Play/Pause** it through the computer's own default output, drag the slider to check a passage, **Prev/Next** to step through the album. A cassette side cannot be edited afterwards any more than a MiniDisc recording can, so it is worth a listen first.

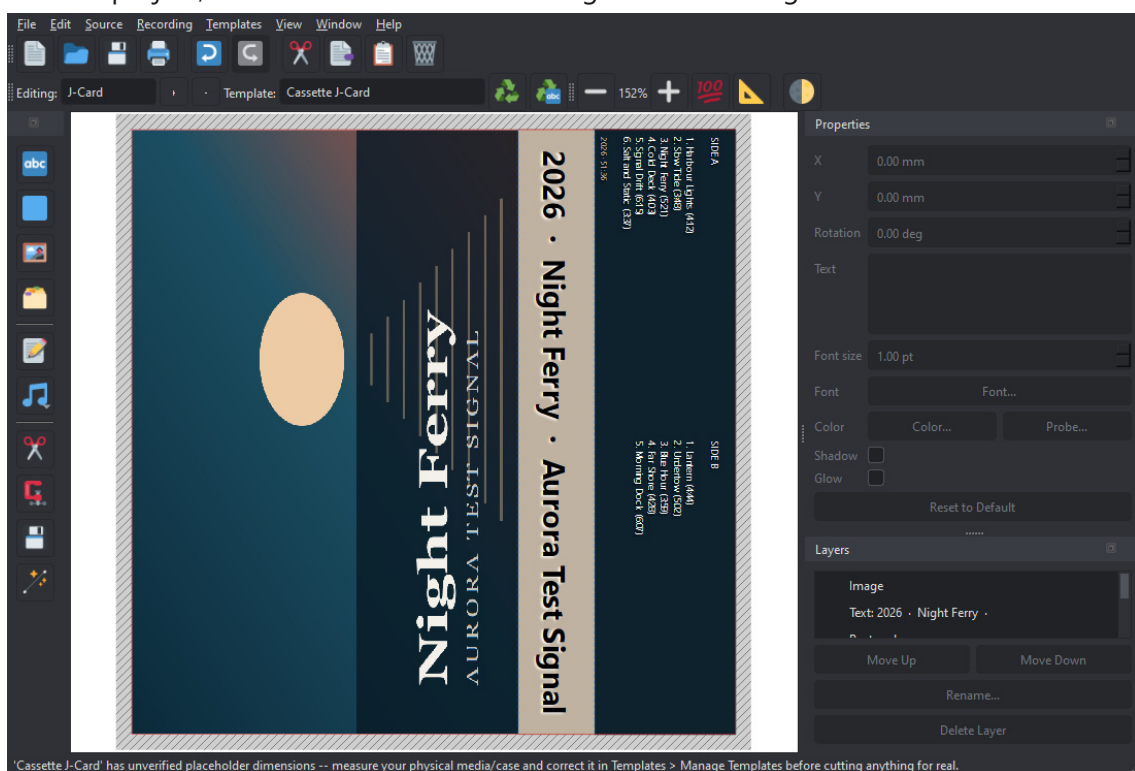

The audio path

Out of the computer and into the deck's line inputs, as an ordinary analogue recording. Nothing in this window depends on how it gets there: the deck's input selector, its recording level and its noise reduction are all yours to set, and xD-Tools neither knows nor asks about any of them.

Set the level with the loudest passage of the album, not the first ten seconds of it. Tape distorts gradually rather than abruptly, so a little too hot is a warmer recording and a lot too hot is a muddy one.

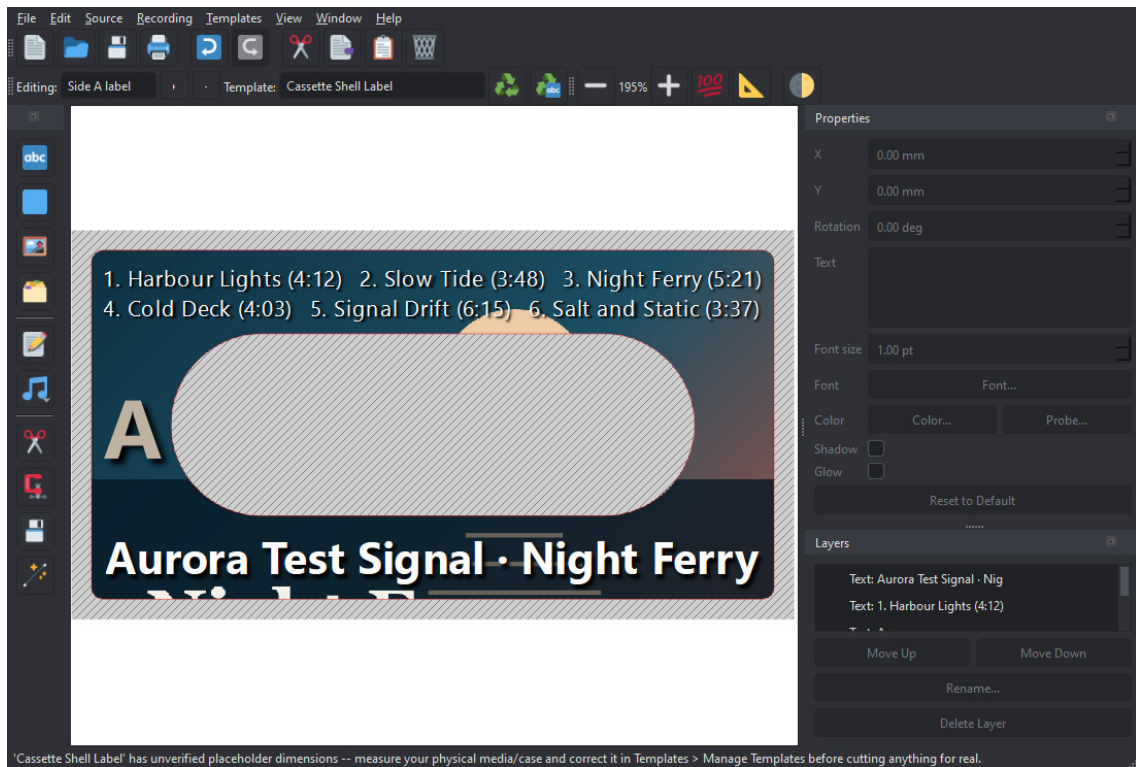

Afterwards

When both sides are done the album is adopted by the open project and its three pages are laid out - the inlay card and a label for each side, split exactly where the recording was. The tape you chose is saved with the project, so the labels and the recording can never disagree about where side B starts.

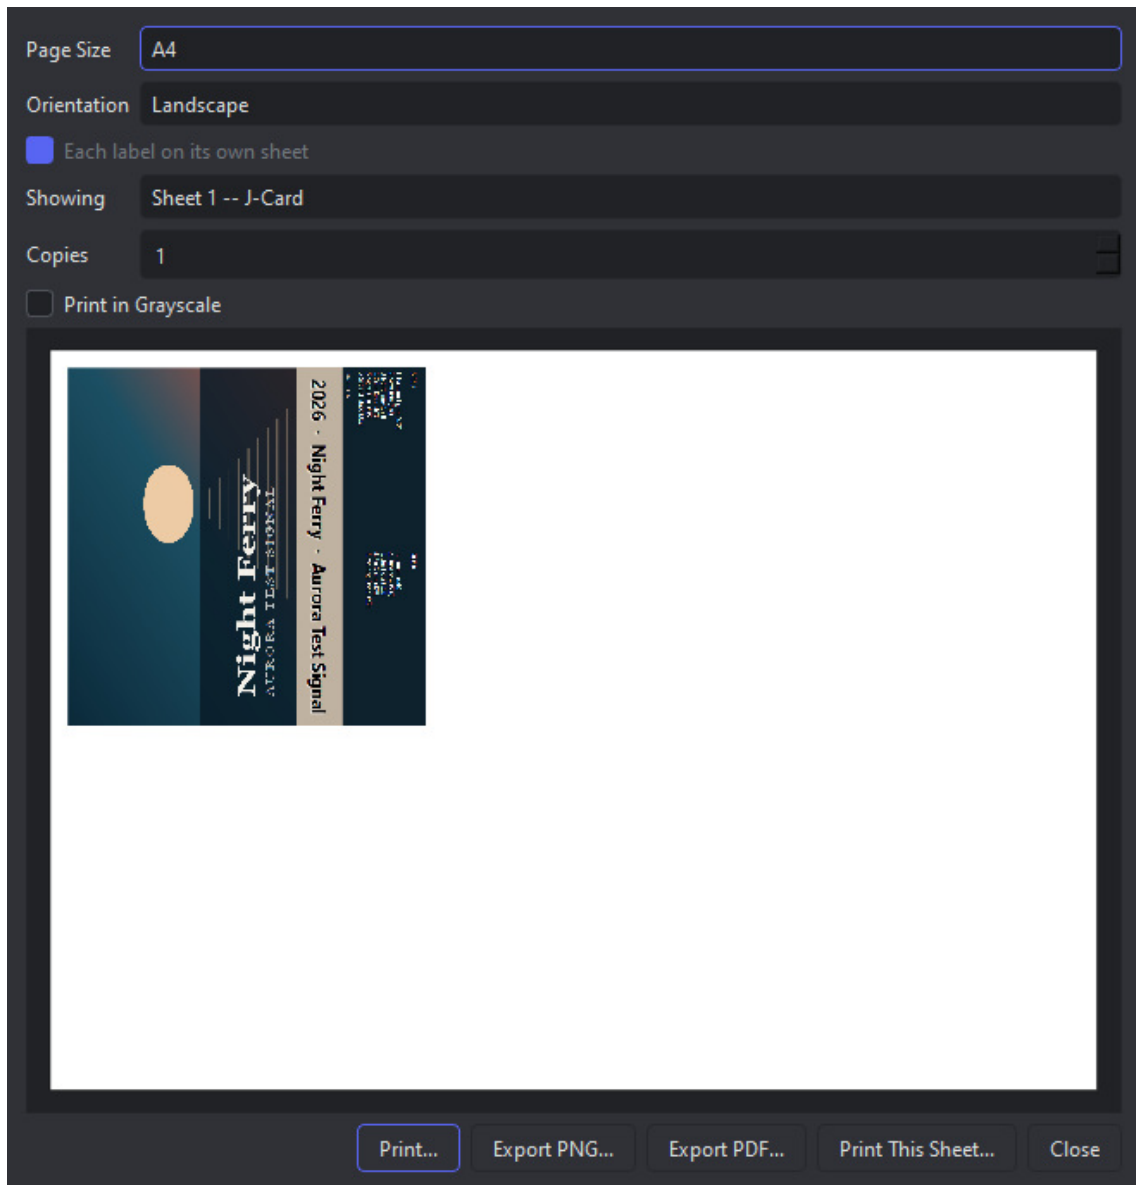

23. The inlay card: cover, spine, and the track list on the tuck-in flap under a heading per side.

The **shell labels** are the other two pages, and they are cut with a round hole for each reel hub - the deck's spindles come up through them, so a label without them would be stuck over the drive. The sleeve goes across the whole sticker, washed out so the text over it stays readable, and the holes are punched through it. The side letter sits between them; that side's tracks run along the bottom, numbered from one so they agree with the deck's own counter.

24. A shell label: the sleeve, the holes the reels turn in, and this side's tracks.

In **File > Print...** the two shell labels share one sheet - they are the same sticker printed twice, cut at the same time and stuck on opposite faces of one tape - and the inlay card, four times the size, takes the next sheet.

25. Both stickers on one sheet, with the inlay on the sheet after it.

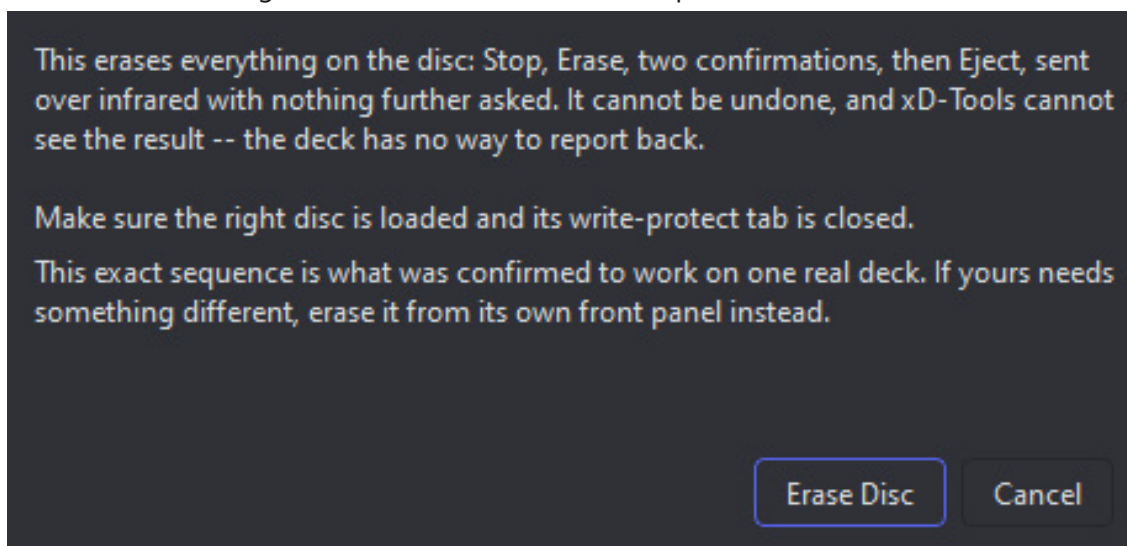

16. Erasing a disc

Erase MiniDisc..., a button on the MiniDisc recording window rather than its own menu entry, clears the disc in the deck - erasing the wrong disc is most likely to come up right before recording onto it, which is where the button now lives.

There is no undo, and xD-Tools cannot see the result. Make sure the disc in the deck is the one you mean, and that its write-protect tab is closed.

A fixed sequence, behind one confirmation

Erase Disc sends **Stop, Erase, Enter, Enter, Eject** over infrared, each key paced a quarter-second behind the last so the deck has time to actually act on one before the next arrives, with nothing further asked once you confirm. This exact sequence - two Enters, then an unconditional Eject - is what was confirmed to work on one real deck; xD-Tools cannot read the display to check how many a different model wants, so if yours needs something else, erase it from its own front panel instead.

26. One confirmation, then the sequence runs on its own.

As with titling, an erase lives in the deck's memory until the disc is ejected - which is why Eject is the last key in the sequence rather than a separate step to remember.

17. Experimental: downloading from a Telegram bot

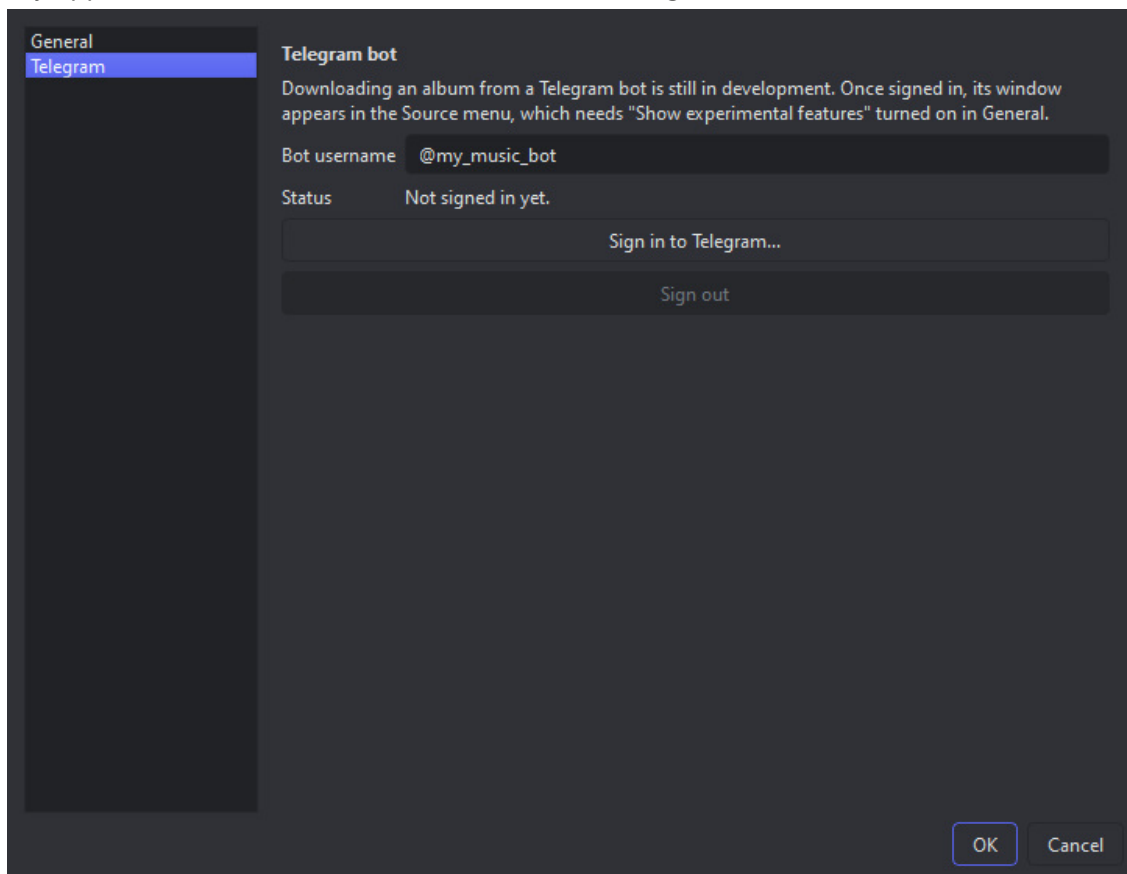

Everything in this chapter is **experimental** and hidden until you ask for it. It works, but it is newer and less exercised than the rest of the program, and the way it is presented may still change.

xD-Tools can hold a conversation with a Telegram bot **you run yourself**, download the files it sends, and hand the result to the recording flow - so a download becomes a recorded, titled disc without leaving the program.

This is for a bot you control. Downloading albums from a public bot that redistributes music without the rights holder's permission is not what this is for, and owning the CD does not make it legal - that covers copying your own disc, not taking a copy from a stranger.

Turning it on

Window > Settings > General has a **Show experimental features** checkbox. It is what makes the bot's own entry appear in the **Source** menu; while it is off, nothing behind it runs.

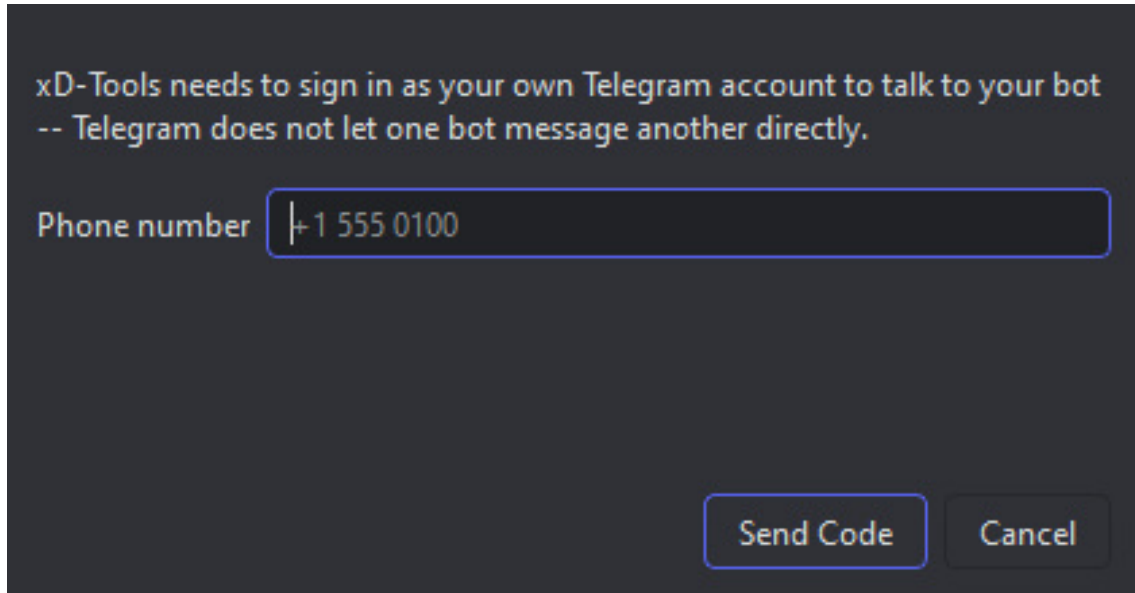

27. Window > Settings, Telegram group. The bot account lives with every other setting rather than in a window of its own.

Window > Settings > Telegram is where the bot lives. **Bot username** is the bot you want to talk to, @something. Downloaded files land in **General > CD rip folder** - the same folder a CD rip uses, since both are raw material for a recording rather than a music library; there is no separate Telegram folder setting any more.

There is no API ID or API Hash to fill in. xD-Tools carries its own, so signing in is the only step. If a build ever ships without them it says so plainly instead of failing to connect.

Signing in

xD-Tools signs in as **your own Telegram account**, not as a bot. That is not a design preference: Telegram's Bot API forbids one bot from messaging another, so the only way to talk to your bot the way a person would is to be a person.

28. Sign in to Telegram. Phone number, then the code Telegram sends you, then a password if you use two-step verification.

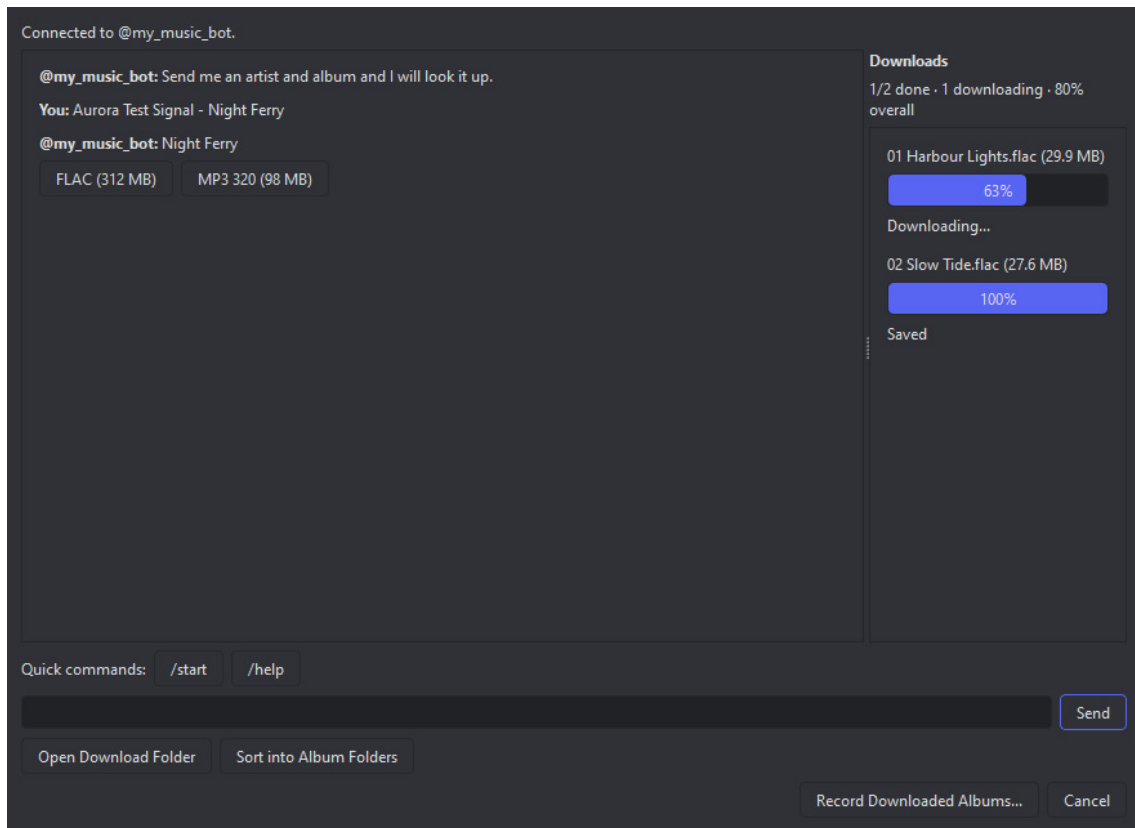

Sign in to Telegram... asks for your phone number, then the code Telegram sends to your other devices, then - if you have two-step verification on - your password. It is the same sequence the Telegram app itself uses.

The sign-in is saved locally, in `telegram.session` next to xD-Tools' own settings. That file is equivalent to being logged in to your account: it is not encrypted, and it is not something to copy onto another machine or send to anyone.

Sign out, next to Sign in, deletes that saved session, so the same Telegram group is also where to leave the account you signed in with.

The conversation

Source > Download Album from Telegram Bot... opens a plain chat. It appears only once a sign-in has been saved and the experimental checkbox is on - it sits beside Rip Audio CD because a download is a source of audio the same way a disc is.

29. The chat, with the download queue on the right.

Deliberately a plain chat rather than a search box: your bot's commands are yours, and xD-Tools cannot know them. So it shows whatever the bot sends and lets you drive it - text, its inline buttons, and any file it attaches. **Quick commands** sends `/start` or `/help` with one click, since almost every bot understands those.

Two conveniences worth knowing. Whatever the bot writes is **translated underneath the original**, into whichever language xD-Tools is set to - the original stays, because a translation can be wrong and an exact command or filename is better read as sent. And a bot that edits its own message to build a menu, rather than sending a new one each time, is followed correctly: the message changes in place, as it does on your phone.

A **photo the bot sends** - cover art, a screenshot, anything that is not a downloadable file attachment - can be clicked once it has finished loading, to save it to disk. Nothing about it joins the download queue below; this is for a one-off image, not an album's worth of files.

The download queue

Files never appear in the conversation - they go to the **queue on the right**, which is the only place a file's name, size, progress and speed are shown. A whole album arriving as twenty attachments would otherwise bury the conversation under twenty near-identical rows.

Downloading starts by itself, and at most three files download at once. A failed one gets a **Retry** button rather than disappearing. A summary line above the queue keeps a running total while several files are in flight - how many are done, queued and downloading, the overall percentage, and the combined speed - so the state of a twenty-file album is one line to glance at rather than twenty rows to add up.

From download to disc

A **FLAC file is filed as it arrives**: its tags are read once it has finished downloading, and it goes straight into its own `Artist - Album` subfolder. So an album downloaded now is already an album folder by the time the last track lands, with nothing to tidy up afterwards.

Anything whose tags cannot say where it belongs stays loose in the download folder: an MP3 or an Ogg (their tags are not read yet), an untagged FLAC, or a file that is not music at all. **Sort into Album Folders** is what deals with those, and with whatever earlier sessions left behind: one subfolder per album, named from the tags, with anything untagged grouped by when it arrived.

Sorting only ever moves audio files. A cover image the bot sent alongside the tracks, or anything else already in that folder, is left exactly where it is. Nor is anything ever overwritten: a name already taken gets a (2).

Record Downloaded Albums... then goes to the recording flow. It sorts first, so you cannot accidentally record two albums onto one disc, and asks which album if there is more than one. From there it is the ordinary recording window "Recording a folder of files" describes - which is also why this needs the MDRem adapter on a MiniDisc project, even though downloading does not.

Open Download Folder opens it in your file manager, for a look before recording.

Both operations exist outside the chat as well, for files downloaded earlier: **Source > Sort Rip/**

Download Folder into Albums... and **Recording > Record from Rip/Download Folder to**

{medium}... - named for the one folder they act on (the same one a CD rip fills) rather than for Telegram specifically, since a folder recorded this way need not have come from the bot at all.

Both buttons go quiet while anything is still downloading - sorting or recording half-written files would be worse than waiting.

18. Troubleshooting

The deck ignores everything

1. **Check the adapter is alive.** Its status LED should be green. Purple means the firmware could not start the hardware at all.
2. **Check it is transmitting.** Point the adapter's LED at a phone camera - infrared shows up as a violet-white dot. The firmware's `BEAM` command lights it steadily for two seconds, which is long enough to see; a single command is 45 ms and invisible.
3. **Check the aim and the distance.** The working range is roughly 20-30 cm, straight at the deck's remote sensor. If you need to be closer than that, the LED current is too low - see the Rd note in the MDRem chapter.
4. **Check the port.** Window > Settings... > Detect. If nothing answers, the adapter is not enumerating - try a different cable.

"Not connected" in the remote window

Something else already has the serial port open. Only one program can hold it at a time - close the other xD-Tools window, dialog, or terminal that is using it.

The new title has the old one stuck on the end

Erase existing titles first was unticked, or the old title was longer than the clearing allowed for. Run the upload again with it ticked.

Two songs ended up as one track

They run into each other with no silence between them, and LEVEL-SYNC had nothing to hear. Record again with **Mark tracks through the adapter** ticked and LEVEL-SYNC off on the deck.

Every track got the same title

This was a real bug and is fixed, but the underlying deck behaviour is worth knowing: the deck is a state machine with no way to ask it anything, and a track number sent while it is paused does not take. That is why the titling sequence sends **Stop** first - it puts the deck in a known state instead of assuming one.

Nothing was saved to the disc

Titles live in the deck's memory until the disc is ejected. Eject it.

No sound, recording or previewing

Recording: check **Window > Settings...** has the right device chosen for the medium you are recording to - MiniDisc and cassette each keep their own, and a device that has since been unplugged shows as **(not connected)** rather than being silently swapped for another one. **Previewing:** the audition player always plays through whatever the operating system currently considers its own default output, regardless of the recording device setting above - check that is the speakers or headphones you expect.

The printed label is the wrong size

Check the printer is not scaling to fit - it must print at 100%. If the canvas itself looks the wrong physical size on screen, that is **Screen DPI** in Window > Settings..., which affects the display only, not the export.

19. Appendix: the MDRem command set

The adapter speaks plain text over its virtual serial port at 115200 baud. Every command answers with a single line - OK, PONG, or ERR <reason> - so a program can parse the reply without knowing the command. Lines beginning with ; are diagnostics.

xD-Tools drives all of this for you. It is documented here for anyone wanting to talk to the adapter directly, from a terminal or their own script.

Command	Does
PING	Answers PONG. This is how the adapter is identified.
HELP	Lists the commands.
KEY <name>	Reports a key's code and bit count. Sends nothing.
SEND <name>	Sends a named key, or a single character.
RAW <hex> [bits]	Sends an arbitrary code. bits defaults to 20.
DUMP <hex> [bits]	Prints the mark/space timings. Sends nothing.
TITLEDISC <text>	Writes the disc title.
TITLETRACK <n> <text>	Writes track n's title.
TIMING ...	Adjusts the timings - including TIMING COUNT, the number of delete presses used to clear a title.
SELFTEST	Checks the carrier. Needs a jumper from GPIO12 to GPIO13.
GPIONTEST	Continuity test for that jumper alone.
BEAM [ms]	Steady carrier, 2000 ms by default - visible in a phone camera.
BLINK [cycles]	The same, blinking, which is easier to spot.

SEND A and SEND a are **different codes**. Single characters are case-sensitive on purpose; key names are not.

How the protocol works

Sony SIRC: a 40 kHz carrier at roughly one-third duty, bits sent least-significant first, a 2400 microsecond start mark, and frames repeating every 45 ms. A '1' is a 1200 microsecond mark, a '0' is 600. Like a real remote, each keypress is sent three times.

The character codes are 20-bit, 0x61D00 with the ASCII value in the low byte - the RM-D10P's own keyboard protocol. The deck's own function keys (Play, Stop, Record, Enter) are **12-bit** codes from a different block. Sending those as 20-bit produces a completely different frame and the deck ignores it.

Things that were tried and do not work

- **Katakana.** The obvious theory - that the character codes are 0x61D00 plus a JIS X 0201 byte, which would put half-width katakana in the unused upper half - was tested against a real deck and refuted. A control 'A' appeared; none of the katakana codes did anything.

- **Delete outside name-edit mode.** On a paused track it does nothing at all. Titles can only be cleared after Name.
- **Holding a key down to clear faster.** The deck's auto-repeat clears four characters in 1.09 s - 272 ms each - against 285 ms for individual presses. About three and a half edit operations per second is a hard ceiling.
